CERTIFICATION OF APPROVAL

CONTINGENCY ANALYSIS OF POWER SYSTEM NETWORKS

by

Mohd Hafiz bin Abdul Rauf

A project dissertation submitted to the
Electrical & Electronics Engineering Programme
Universiti Teknologi PETRONAS
in partial fulfilment of the requirement for the
Bachelor of Engineering (Hons)
(Electrical & Electronics Engineering)

Approved:

[Signature]

14.12.2006

Professor Dr Ramiah Jegatheesan
Project Supervisor

UNIVERSITI TEKNOLOGI PETRONAS
TRONOH, PERAK

December 2006
CERTIFICATION OF ORIGINALITY

This is to certify that I am responsible for the work submitted in this project, that the original work is my own except as specified in the references and acknowledgements, and that the original work contained herein have not been undertaken or done by unspecified sources or persons.

Mohd Hafiz bin Abdul Rauf
ABSTRACT

In this modern power system, planning and construction of the system with outage minimization as a major design criterion is becoming more important. However, even with the best possible construction and operating practices, outages still can occur. Several techniques have been developed to analyze the status of the system after the real outage occurs. This project presents an alternative way of conducting power flow analysis in determining the new bus voltages and line currents during outage occurrence. The algorithms have been accommodated in one complete program making it an effective tool for contingency analysis. The program has been tested on an IEEE bus test case and the remarkable results obtained in terms of its reduced computation time and accuracy showed that this technique could be implemented, particularly when involving practical work with a lot of calculations.
ACKNOWLEDGEMENTS

This dissertation could not have been written without Dr. Ramiah Jegatheesan who not only served as my supervisor but also encouraged and challenged me throughout my academic program as well as this project. He patiently guided me through the dissertation process, never accepting less than my best efforts.

Finally, I would like to thank my mother and father, who gave me the opportunity and the spirit to educate myself. Mom, Dad, you are the best. To all my sisters and little brother, I hope I can serve as inspiration to all of you. If I can do it, so can you.

CHAPTER 1
INTRODUCTION

Line outages, whether it is planned or unplanned are the common issue in power system networks. That is why planning and construction of the system with outage minimization as a major design criterion is becoming more important and more common. Of course, the primary requirements of a reliable power system are the proper line construction and maintenance and proper over-current device placement and coordination [1]. Nevertheless, even with the best possible construction and operating practices, outages still can occur.

Whenever an outage occurs, an effective and economical way to improve the reliability of the power system is by restoring the power temporarily using alternative feeds [1]. However, what it more important is to determine the status of the system when any possible line outages occur. This is the point where many techniques of power system analysis have been introduced and developed, such as power flow analysis, contingency analysis, system restoration, load shedding, etc [2].

A system contingency can be defined as a disturbance that can occur in the network and can result in possible loss of parts of the network like buses, lines, transformers or power unit in any of the network areas. Contingency analysis is an evaluation of an existing or proposed electrical distribution system to determine the capability of the system to restore power using alternative feeds [1]. It is performed to assess the status of the power system network for any possible line outage before it is actually occurs.

When a line is switched onto or off the system through the action of circuit breakers, line currents are redistributed throughout the network and bus voltages change. These new steady steady-state bus voltages and line currents can be predicted quickly by what is called the contingency analysis program [6]. The large-
scale network models used for this type of evaluation, like those used for fault
calculations, do not have to be exact because the system planners and operators,
who must undertake hundreds of studies in a short time period, are more concerned
with knowing if overload levels of current and out-of-limit voltages and power flow
exist than with finding the exact values of those quantities [6].

This project aimed at developing the Contingency Analysis program, to
calculate new steady state bus voltages and line currents during the line outage and
other contingencies. The program uses the factored matrices of Bus Admittance
Matrix algorithm, which is the main advantage of this program. It is written and
demonstrated in MATLAB. In realizing the effectiveness of the developed program,
validation was performed on an IEEE Bus System and the results were compared to
the results using the traditional power flow analysis and it indicates a remarkable
advantage particularly in its computation time and the accuracy. Results obtained
from the studies indicated the proposed technique could be implemented, particularly
when involving practical work with a lot of calculations.
CHAPTER 2
LITERATURE REVIEW

Power system network can be characterized by two methods namely, Bus Impedance Matrix, \( Z_{\text{bus}} \) and Bus Admittance Matrix, \( Y_{\text{bus}} \), which are inverse of each other. Practically, it is much easier to construct the bus admittance matrix, rather than bus impedance matrix.

2.1 Bus Impedance Matrix \( Z_{\text{bus}} \) [4]

Bus Impedance Matrix, \( Z_{\text{bus}} \) of a power network can be obtained by inverting the bus admittance matrix, \( Y_{\text{bus}} \), which is easy to construct. However, when the order of matrix is large, direct inversion requires more core storage and enormous computer computation time. Therefore, inversion of \( Y_{\text{bus}} \) is prohibited for large size network.

\( Z_{\text{bus}} \) can be constructed by adding the network elements one after another. Using impedance parameters, performance equations in bus frame of reference can be written as:

\[
E_{\text{bus}} = Z_{\text{bus}} I_{\text{bus}} \tag{1}
\]

In expanded form, the above becomes

\[
\begin{bmatrix}
E_1 \\
E_2 \\
\vdots \\
E_N
\end{bmatrix} =
\begin{bmatrix}
Z_{11} & \cdots & \cdots & Z_{1N} \\
Z_{21} & Z_{22} & \cdots & Z_{2N} \\
\vdots & \vdots & \ddots & \vdots \\
Z_{N1} & Z_{N2} & \cdots & Z_{NN}
\end{bmatrix}
\begin{bmatrix}
I_1 \\
I_2 \\
\vdots \\
I_N
\end{bmatrix} \tag{2}
\]

From this we can write

\[
E_p = Z_{p1} I_1 + Z_{p2} I_2 + \ldots + Z_{pq} I_q + \ldots + Z_{pn} I_N \tag{3}
\]
By injecting 1 p.u. current at bus $q$ and other bus currents are set to zero, we can obtained the $Z_{pq}$ by measuring $E_p$. The indices $p$ and $q$ can be varied from 1 to $N$.

When constructing $Z_{bus}$ building algorithm, elements are added one by one. At any stage, the added element may be a branch or a link. A branch is the added element which will create a new bus in the network. On the other hand, by adding link, no new bus will be created.

As given in [4], the summary of the Bus Impedance Matrix algorithm formulas are as Table 1 below:

<table>

2.2 Power Flow Analysis

Power flow analysis, also known as load flow, is an important part of power system analysis. It serves the purpose of planning, control of existing system as well as planning its future expansion [5]. Unlike traditional circuit analysis, a power flow study usually uses simplified notation such as a one-line diagram and per-unit system, and focuses on various forms of AC power (i.e. reactive, real, and apparent) rather than voltage and current.

The great importance of power flow or load-flow studies is in the planning the future expansion of power systems as well as in determining the best operation of existing systems. The principal information obtained from the power flow study is the magnitude and phase angle of the voltage at each bus and the real and reactive power flowing in each line.

When conducting a power flow analysis, the system is assumed to be operating under balanced conditions and a single phase model is used. Four quantities are associated with each bus. These are voltage magnitude $|V|$, phase angle $\delta$, real power $P$, and reactive power $Q$. Generally, the system buses can be classified into 3 types: [5]

1) **Slack bus**
   It also known as slack or swing bus, which will be the reference bus. In slack bus, voltage magnitude and phase angle are specified.

2) **Load buses (P - Q buses)**
   In these buses the active and reactive power are specified.

3) **Regulated buses (P - V buses)**
   These buses are the generator buses, where the real power and voltage magnitude are specified.

There are several solutions, or methods introduced to solve for the power flow analysis problem, namely:

1) **Gauss-Seidel Method**
2) **Newton-Raphson Method**
3) **Fast Decoupled Method**
2.3 Graphical User Interface (GUI)

A graphical user interface (GUI) is a graphical display that contains devices, or components, that enable a user to perform interactive tasks. To perform these tasks, the user of the GUI does not have to create a script or type commands at the command line. Often, the user does not have to know the details of the task at hand.

The GUI components can be menus, toolbars, push buttons, radio buttons, list boxes, and sliders. In MATLAB, a GUI can also display data in tabular form or as plots, and can group related components. The following figure illustrates a simple GUI.

This project will utilize this MATLAB's feature to make the program more user-friendly and thus make it easier for conducting the analysis.

![Figure 1: A simple GUI using MATLAB](image)

Figure 1: A simple GUI using MATLAB
CHAPTER 3
METHODOLOGY

In contingency analysis, the network models used do not have to be exact because the power engineers and system operators are more interested in knowing whether or not an insecure or vulnerable condition exists in the steady state following any of the outages.

Therefore, several approximations are made. Often, the resistance is considered negligible and the network model becomes purely reactive. Line charging and off-nominal tap charging of transformers are also omitted [6]. Accordingly, to test for the effects of line and transformer outages on the bus voltages and line flows in the network, approximate ac power-flow techniques are generally employed since they can provide a fast solution of the many test cases which need to be run.

In many cases, linear models are considered satisfactory and the principle of superposition is then employed. Methods of contingency analysis which used the factored Bus Admittance Matrix (\(Y_{\text{bus}}\)) becomes attractive from computational viewpoint, especially if the loads can be treated as constant current injections into the various buses of the system [6]. Hence, the concept of compensating currents is developed, to allow the use of existing system \(Z_{\text{bus}}\) without having to modify it whenever a contingency occurs.

3.1 Bus Admittance Matrix

While doing symmetrical short circuit analysis, the bus impedance matrix \(Z_{\text{bus}}\) is employed. However, when the system is large, construction of \(Z_{\text{bus}}\) matrix itself is tedious. Furthermore, since \(Z_{\text{bus}}\) matrix is always full, more computer storage is required to store the matrix. Moreover, modification of the system such as removal or addition of one link calls for recalculation of all the elements in \(Z_{\text{bus}}\) matrix.
On the other hand, the bus admittance matrix $Y_{bus}$ can be easily obtained even for large power system network. The main advantage of this matrix is that, it is always sparse (having many elements of zero) and thus requires less storage capacity. For instance, whenever an element $a - b$ is added, only four elements $Y_{aa}$, $Y_{bb}$, $Y_{ab}$ and $Y_{ba}$ need to be modified and the other elements in the $Y_{bus}$ matrix remain unaltered.

### 3.1.1 Bus Admittance Matrix building algorithm [6]

This matrix can be build by adding one element at a time. To start with, all the elements of bus admittance matrix are assumed to be zero. Then, when a network element of admittance $y_{ab}$ is added between buses $p$ and $q$, **ONLY 4 elements** of bus admittance matrix are to be modified as below.

\[
\begin{align*}
Y_{pp\, new} &= Y_{pp\, old} + y_{ii} \\
Y_{qq\, new} &= Y_{qq\, old} + y_{ii} \\
Y_{pq\, new} &= Y_{pq\, old} + y_{ii} \\
Y_{qp\, new} &= Y_{qp\, old} + y_{ii}
\end{align*}
\]  \hspace{1cm} (4)

Even with the orientation is from bus $q$ to $p$, the result will be the same. However, if bus $q$ happens to be reference bus, then $Y_{pp}$ alone gets modified as:

\[
Y_{pp\, new} = Y_{pp\, old} + y_{ii}
\]  \hspace{1cm} (5)

i.e. if $y_{p\theta}$ is connected between bus $p$ and reference bus, then

\[
Y_{pp\, new} = Y_{pp\, old} + y_{p\theta}
\]  \hspace{1cm} (6)

This method of constructing the bus admittance matrix by adding the elements one by one and modifying the bus admittance matrix each time, is very well suited for large network. Each time, one network element data is read and the bus admittance matrix is updated. When all the network elements are added, the final bus admittance matrix will be obtained.

When any fault occurs at $p^{th}$ bus, only the $p^{th}$ column of the $Z_{bus}$ matrix and not the full $Z_{bus}$ matrix is needed. However, it is also possible to obtain the $p^{th}$ column of $Z_{bus}$ matrix, $Z_{bus}^{(p)}$ from the $Y_{bus}$ matrix. In fault study, the bus at which the
fault occurs (value of \( p \)) may keep changing. Therefore, if the \( Y_{bus} \) is factored and the factored matrices are available, any required column of \( Z_{bus} \) matrix can be obtained easily.

The \( p^{th} \) column of the \( Z_{bus} \) matrix, \( Z_{bus}^{(p)} \) can be obtained from the factor matrices of \( Y_{bus} \) matrix. Previously, we know already that

\[
Z_{bus} I_{bus} = V_{bus}
\]  

Thus,

\[
\begin{bmatrix}
Z_{11} & Z_{12} & \cdots & Z_{1p} & \cdots & Z_{1N} \\
Z_{21} & Z_{22} & \cdots & Z_{2p} & \cdots & Z_{2N} \\
\vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\
Z_{p1} & Z_{p2} & \cdots & Z_{pp} & \cdots & Z_{pN} \\
Z_{N1} & Z_{N2} & \cdots & Z_{Np} & \cdots & Z_{NN}
\end{bmatrix}
\begin{bmatrix}
I_1 \\
I_2 \\
\vdots \\
I_p \\
\vdots \\
I_N
\end{bmatrix}
= 
\begin{bmatrix}
V_1 \\
V_2 \\
\vdots \\
V_p \\
\vdots \\
V_N
\end{bmatrix}
\]  

Consider the bus current vector:

\[
I_{bus} = \begin{bmatrix}
I_1 \\
I_2 \\
\vdots \\
I_p \\
\vdots \\
I_N
\end{bmatrix} = \begin{bmatrix}
0 \\
0 \\
\vdots \\
1 \\
\vdots \\
0
\end{bmatrix} \quad \text{and denote this as } I_p
\]  

Substituting \( I_{bus} = I_p \) in the equation (8), we will get

\[
\begin{bmatrix}
Z_{1p} \\
Z_{2p} \\
\vdots \\
Z_{pp} \\
Z_{Np}
\end{bmatrix}
= 
\begin{bmatrix}
V_1 \\
V_2 \\
\vdots \\
V_p \\
V_N
\end{bmatrix}
\quad \text{i.e. } Z_{bus}^{(p)} = Z_{bus}^{(p)}
\]  

Thus, by injecting 1 p.u current at bus \( p \) and set the other currents to be zero \((I_{bus} = I_p)\), \( Z_{bus}^{(p)} \) is numerically equal to \( V_{bus} \) obtained from (7). The inverse form of (7) is \( Y_{bus} V_{bus} = I_{bus} \).
In the subsequent chapters, we will see how the $Y_{bus}$ is factorized and how the factored matrices are used to obtained the $p^{th}$ column of the $Z_{bus}$.

3.1.2 Factored Matrices of $Y_{bus}$ Matrix [6]

This is the important part of the program. Once the factored matrices of $Y_{bus}$ matrix are obtained, any required column of the $Z_{bus}$ can be extracted easily.

The symmetrical matrix $Y_{bus}$ can be factored as:

$$Y_{bus} = LDL'$$

where $L$ is a lower triangular matrix

$D$ is a diagonal matrix

$L'$ is the transpose of $L$ matrix

Because of $Y_{bus} = LDL'$, we can state that:

$Z_{bus}^{(p)}$ is numerically equal to $V_{bus}$ obtained from $LDL'V_{bus} = I_{bus}$, for $I_{bus} = I_p$.

If the fault occurs at some other bus, say $k$, then $Z_{bus}^{(k)}$ can be obtained by solving $LDL'V_{bus} = I_{bus}$ for $V_{bus}$ taking $I_{bus} = I_k$. This calculation requires only back substitution as the factor matrices are already available. Thus, only a repeat solution is carried out with different values for right hand side vector.

Let us consider a 4 bus system described by:

$$
\begin{bmatrix}
Y_{11} & Y_{21} & Y_{31} & Y_{41} \\
Y_{12} & Y_{22} & Y_{32} & Y_{42} \\
Y_{13} & Y_{23} & Y_{33} & Y_{43} \\
Y_{14} & Y_{24} & Y_{34} & Y_{44}
\end{bmatrix}
\begin{bmatrix}
V_1 \\
V_2 \\
V_3 \\
V_4
\end{bmatrix}
= 
\begin{bmatrix}
I_1 \\
I_2 \\
I_3 \\
I_4
\end{bmatrix}
$$

(12)

The coefficient matrix $Y_{bus}$ can be written as the product of three matrices $L$, $D$ and $L'$. Therefore, $Y_{bus} = LDL'$.  

(13)
Matrix $L$ is a lower triangular matrix of the form

$$L = \begin{bmatrix}
1 & 0 & 0 & 0 \\
\ell_{21} & 1 & 0 & 0 \\
\ell_{31} & \ell_{32} & 1 & 0 \\
\ell_{41} & \ell_{42} & \ell_{43} & 1
\end{bmatrix}$$

and matrix $D$ is a diagonal matrix of the form

$$D = \begin{bmatrix}
d_{11} & 0 & 0 & 0 \\
0 & d_{22} & 0 & 0 \\
0 & 0 & d_{33} & 0 \\
0 & 0 & 0 & d_{44}
\end{bmatrix}$$

The matrix $L'$ is only the transpose of matrix $L$.

$$L' = \begin{bmatrix}
1 & \ell_{21} & \ell_{31} & \ell_{41} \\
0 & 1 & \ell_{32} & \ell_{42} \\
0 & 0 & 1 & \ell_{43} \\
0 & 0 & 0 & 1
\end{bmatrix}$$

Thus, using equation (14) and (15) in equation (13), $Y_{bus}$ can also be written as:

$$Y_{bus} = \begin{bmatrix}
1 & 0 & 0 & 0 \\
\ell_{21} & 1 & 0 & 0 \\
\ell_{31} & \ell_{32} & 1 & 0 \\
\ell_{41} & \ell_{42} & \ell_{43} & 1
\end{bmatrix} \begin{bmatrix}
d_{11} & 0 & 0 & 0 \\
0 & d_{22} & 0 & 0 \\
0 & 0 & d_{33} & 0 \\
0 & 0 & 0 & d_{44}
\end{bmatrix} \begin{bmatrix}
1 & \ell_{21} & \ell_{31} & \ell_{41} \\
0 & 1 & \ell_{32} & \ell_{42} \\
0 & 0 & 1 & \ell_{43} \\
0 & 0 & 0 & 1
\end{bmatrix} = \begin{bmatrix}
Y_{11} & Y_{21} & Y_{31} & Y_{41} \\
Y_{12} & Y_{22} & Y_{32} & Y_{42} \\
Y_{13} & Y_{23} & Y_{33} & Y_{43} \\
Y_{14} & Y_{24} & Y_{34} & Y_{44}
\end{bmatrix}$$

After multiplying first 2 matrices, the result as follows:

$$Y_{bus} = \begin{bmatrix}
d_{11} & 0 & 0 & 0 \\
\ell_{21}d_{11} & d_{22} & 0 & 0 \\
\ell_{31}d_{11} & \ell_{32}d_{22} & d_{33} & 0 \\
\ell_{41}d_{11} & \ell_{42}d_{22} & \ell_{43}d_{33} & d_{44}
\end{bmatrix} \begin{bmatrix}
1 & \ell_{21} & \ell_{31} & \ell_{41} \\
0 & 1 & \ell_{32} & \ell_{42} \\
0 & 0 & 1 & \ell_{43} \\
0 & 0 & 0 & 1
\end{bmatrix} = \begin{bmatrix}
Y_{11} & Y_{21} & Y_{31} & Y_{41} \\
Y_{12} & Y_{22} & Y_{32} & Y_{42} \\
Y_{13} & Y_{23} & Y_{33} & Y_{43} \\
Y_{14} & Y_{24} & Y_{34} & Y_{44}
\end{bmatrix}$$
By looking to the above equations, we can generalize the equations to obtain the elements of the matrices. The equations are as follows:

\[ d_{ii} = Y_{ii} - \sum_{k=1}^{i-1} \ell_{ik}^2 d_{kk} \]  
\[ \ell_{ij} = (Y_{ij} - \sum_{k=1}^{i} \ell_{ik} d_{kk} \ell_{jk}) / d_{ii} \]  

The elements of the factor matrices \( L \) and \( D \) can be obtained using equations (18) and (19). For matrix of order \( N \), the elements of factor matrices \( L \) and \( D \) are calculated in the order:

\[ d_{ii}, \ell_{i+1}, \ell_{i+2}, \ldots, \ell_{N} \]  

for \( i = 1, 2, 3, \ldots, N \)

(20)

The \( L \) and \( D \) matrices are combined into one matrix only, to reduce the computer storage.

\[
\begin{bmatrix}
  d_{11} & 0 & 0 & 0 \\
  \ell_{21} & d_{22} & 0 & 0 \\
  \ell_{31} & \ell_{32} & d_{33} & 0 \\
  \ell_{41} & \ell_{42} & \ell_{43} & d_{44}
\end{bmatrix}
\]  

(21)

3.1.3 Solving \( Y_{bus} V_{bus} = I_{bus} \) for \( V_{bus} \) using the factor matrices [6]

Now the problem is to solve for vector \( V_{bus} \) for a given value of vector \( I_{bus} \) using

\[ LDL'V_{bus} = I_{bus}. \]  

(22)

Let us define two intermediate dummy vectors \( V' \) and \( V'' \) as

\[ L' = V' \]  
\[ DV' = V'' \]  

(23)

(24)

Then \( LV'' = I_{bus} \)

(25)

In order to solve for the unknown voltage vector \( V_{bus} \), the three equations above must be solved in the order equation (25), (24) and (23).
For a 4 bus system, equation (25) is:
\[
\begin{bmatrix}
    d_{11} & 0 & 0 & 0 \\
    \ell_{21} & d_{22} & 0 & 0 \\
    \ell_{31} & \ell_{32} & d_{33} & 0 \\
    \ell_{41} & \ell_{42} & \ell_{43} & d_{44}
\end{bmatrix}
\begin{bmatrix}
    V_1^- \\
    V_2^- \\
    V_3^- \\
    V_4^-
\end{bmatrix}
= 
\begin{bmatrix}
    I_1 \\
    I_2 \\
    I_3 \\
    I_4
\end{bmatrix}
\]  
(26)

The elements of $V''$ vector are calculated using the equation below:
\[
V_{i''} = I_i - \sum_{k=1}^{N} \ell_{ik} V_k \quad i = 1, 2, \ldots, N
\]  
(27)

Now equation (24) can be written as:
\[
\begin{bmatrix}
    d_{11} & 0 & 0 & 0 \\
    0 & d_{22} & 0 & 0 \\
    0 & 0 & d_{33} & 0 \\
    0 & 0 & 0 & d_{44}
\end{bmatrix}
\begin{bmatrix}
    V_1^- \\
    V_2^- \\
    V_3^- \\
    V_4^-
\end{bmatrix}
= 
\begin{bmatrix}
    V_1^- \\
    V_2^- \\
    V_3^- \\
    V_4^-\end{bmatrix}
\]  
(28)

From this equation, it is clear that the elements of $V'$ vector are calculated using the equation below:
\[
V_{i'} = V_{i''} / d_i \quad i = 1, 2, \ldots, N
\]  
(29)

Finally, equation (23) can be written in the form of
\[
\begin{bmatrix}
    1 & \ell_{21} & \ell_{31} & \ell_{41} \\
    0 & 1 & \ell_{32} & \ell_{42} \\
    0 & 0 & 1 & \ell_{43} \\
    0 & 0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
    V_1^- \\
    V_2^- \\
    V_3^- \\
    V_4^-
\end{bmatrix}
= 
\begin{bmatrix}
    V_1^- \\
    V_2^- \\
    V_3^- \\
    V_4^-
\end{bmatrix}
\]  
(30)

From this equation, we can generalize that
\[
V_i = V_i' - \sum_{k=1}^{N} \ell_{ik} V_k \quad i = N, N-1, \ldots, 1
\]  
(31)

It is to be noticed that, while calculating elements of vector $V_{bus}$, from the above equation, $V_i$'s are computed in the order of $i = N, N-1, \ldots, 1$.
3.1.4 Summary of formulas

Elements of factor matrices are calculated from

\[ d_{ij} = Y_{ij} - \sum_{k=1}^{l-1} \ell_{ik} d_{jk} \quad \text{and} \quad \ell_{ij} = (Y_{ij} - \sum_{k=1}^{l-1} \ell_{ik} d_{jk}) / d_{ij} \]

following the order \( d_1, \ell_{i+1}, \ell_{i+2}, \ldots, \ell_N \) for \( i = 1, 2, \ldots, N \)

\( V_{bus} \) solution is obtained from these equations:

\[
V_i = I_i - \sum_{k=1}^{l-1} \ell_{ik} V_k \quad i = 1, 2, \ldots, N 
\]

(32)

\[
V_i = V_i / d_{ij} \quad i = 1, 2, \ldots, N 
\]

(33)

\[
V_i = V_i - \sum_{k=i+1}^{N} \ell_{ik} V_k \quad i = N, N-1, \ldots, 1 
\]

(34)

3.1.5 Calculation of the vector \( Z_{bus}^{(m-n)} \) from factors of \( Y_{bus} \) matrix [6]

In contingency analysis, if a contingency occur between line \( m \) and \( n \), we need to calculate the difference of the two vectors \((Z_{bus}^{(m)} - Z_{bus}^{(n)})\) where \( Z_{bus}^{(m)} \) and \( Z_{bus}^{(n)} \) are the \( m^{th} \) and \( n^{th} \) column of the bus impedance matrix \( Z_{bus} \), respectively.

Let \( Z_{bus}^{(m-n)} = Z_{bus}^{(m)} - Z_{bus}^{(n)} \)

(35)

Again let us define vector \( I_{(m-n)} \) as

\[
I_{(m-n)} = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 1 & 0 \\ m & \cdots & 0 & 1 \\ 0 & \cdots & n-1 & 0 \\ \vdots & \ddots & \ddots & \vdots \\ N & 0 & \cdots & 0 \end{bmatrix} 
\]

(36)
In $V_{bus} = Z_{bus} I_{bus}$, if $I_{bus} = 1_{(m-n)}$ (1 p.u current is injected at bus $m$ and -1 p.u current is injected at bus $n$), then the resultant vector will be the difference of the $m^{th}$ and $n^{th}$ column of the $Z_{bus}$, respectively.

Thus $Z_{bus}^{(m-n)}$ is numerically equals to $V_{bus}$, obtained from $V_{bus} = Z_{bus} I_{bus}$ for $I_{bus} = 1_{(m-n)}$. Equivalently, $Z_{bus}^{(m-n)}$ can be obtained solving $Y_{bus} V_{bus} = I_{bus}$ for $V_{bus}$ corresponding to $I_{bus} = 1_{(m-n)}$.

Knowing that $Y_{bus}$ can be factored as $LDL'$, we can now state that $Z_{bus}^{(m-n)}$ can be obtained by solving $LDL' V_{bus} = I_{bus}$ for $V_{bus}$ corresponding to $I_{bus} = 1_{(m-n)}$.

3.2 Addition of one line [6]

When considering line addition to or removal from an existing system, it is not always necessary to build a new $Z_{bus}$ or to calculate new triangular factors of $Y_{bus}$, especially if the only interest is to establish the impact of the changes on bus voltages. This is where the compensating currents concept is developed as an alternative procedure. The compensating currents are injected into the existing system to account for the effect of the line changes.

Consider the original system with voltages $V_1$, $V_2$, ..., $V_N$ due to current injection $I_1$, $I_2$, ..., $I_N$ as illustrated in figure 2 below:

![Figure 2: Original System](image_url)
We assume that the bus voltages $V_1, V_2, ..., V_N$ produced in the original system by the current injections $I_1, I_2, ..., I_N$ are known. Suppose that a line of impedance $z_a$ is added between buses $m$ and $n$. The current injections are fixed in value and therefore are unaffected by the addition of line of impedance $z_a$. Let the changed bus voltages be $V_1', V_2', ..., V_m', ..., V_n', ..., V_N'$ as shown in Figure 4 on the next page.

Addition of line causes a current flow of $I_a$ as shown in Figure 3. We have

$$z_a I_a = V_{bus} - V_n'$$

$$m \begin{bmatrix} V_1' \\ V_2' \\ \vdots \\ V_m' \\ V_n' \\ \vdots \\ V_N' \end{bmatrix} = \begin{bmatrix} 0 & \cdots & 0 & 1 & 0 & \cdots & 0 & -1 & 0 & \cdots & 0 \end{bmatrix} \begin{bmatrix} V_1 \\ V_2 \\ \vdots \\ V_m \\ V_n \\ \vdots \\ V_N \end{bmatrix}$$

(37)
Defining
\[ A_c = \begin{bmatrix} 0 & \ldots & 0 & 1 & 0 & \ldots & 0 & -1 & 0 & \ldots & 0 \end{bmatrix} \]
we get
\[ z_a I_a = A_c V_{bus} \quad (39) \]

The effect of current \( I_a \) shown in Figure 3 can be replaced by current injection of \(-I_a\) at bus \( m \) and \( I_a \) at bus \( n \) as shown in Figure 4. By examining Figure 4, it reveals that the bus voltages \( V_1', V_2', \ldots, V_N' \) are due to:

1) Current injections \( I_1, I_2, \ldots, I_N \) and
2) Current injections \(-I_a\) at bus \( m \) and \( I_a \) at bus \( n \)

Hence, to determine the bus voltages \( V_1', V_2', \ldots, V_N' \) we shall now apply the Superposition Theorem. When current injections \( I_1, I_2, \ldots, I_N \) alone are there, bus voltages will be the same as the bus voltages in the original system (refer Figure 2) denoted by \( V_{bus} \). When current injections \(-I_a\) at bus \( m \) and \( I_a \) at bus \( n \) are alone there, bus voltages will be equal to \( Z_{bus} I_{comp} \) where

\[ I_{comp} = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ -I_a \\ 0 \\ \vdots \\ I_a \\ 0 \\ \vdots \\ 0 \end{bmatrix} = - \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \\ 0 \\ \vdots \\ -1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} I_a = -A_c I_a \quad (40) \]

Therefore,
\[ V'_{bus} = V_{bus} + Z_{bus} I_{comp} = V_{bus} - Z_{bus} A_c I_a \quad (41) \]

\( V_{bus} \) can be obtained combining equation (39) and equation (41).
Substituting equation (41) into (39),

\[ z_a I_a = A_c V_{bus} - A_c Z_{bus} A_c' I_a \]  

(42)

Defining \( Z = z_a + A_c Z_{bus} A_c' \)

(43)

we get \( Z I_a = V_m - V_n \), thus we get

\[ I_a = (V_m - V_n) / Z \]  

(44)

Now equation (41) can be written as

\[ V'_{bus} = V_{bus} + \Delta V \]  

(45)

Where \( \Delta V = -Z_{bus} A_c' I_a \)  

(46)

Thus, new bus voltages \( V'_{bus} \) can be written as follows:

1) Calculate \( Z \) from equation (43)
2) Calculate \( I_a \) from equation (44)
3) Calculation \( \Delta V \) from equation (46)
4) Calculation \( V'_{bus} \) from equation (45)

Note that equation (42) and (45) contain \( Z_{bus} \), the bus impedance matrix of the system, which is not available. Let us now see how this could be overcome.

**Calculation of \( Z \)**

Let us note that \( A_c = \begin{bmatrix} 0 & \cdots & 0 & 1 & 0 & \cdots & 0 & -1 & 0 & \cdots & 0 \end{bmatrix}^{m \times n} \)

\[ Z = z_a + A_c Z_{bus} A_c' \]

\[ = z_a + A_c Z_{bus}^{(m-n)} \]  

(47)

Denoting \( m \left[ Z_{bus}^{(m-n)} \right] \) is the \( m \)th element of \( Z_{bus}^{(m-n)} \) and \( n \left[ Z_{bus}^{(m-n)} \right] \) is the \( n \)th element of \( Z_{bus}^{(m-n)} \) the above equation becomes

\[ Z = z_a + m \left[ Z_{bus}^{(m-n)} \right] - n \left[ Z_{bus}^{(m-n)} \right] \]  

(48)
Calculation of $I_a$

$$I_a = \frac{(V_m - V_n)}{Z} \quad (49)$$

Calculation of $\Delta V$

$$\Delta V = -Z_{bus} A^t J_a \quad (50)$$

Calculation of new bus voltage $V'_{bus}$

$$V'_{bus} = V_{bus} + \Delta V \quad (51)$$

It is to be noted that for the above calculations we need only the vector $Z_{bus}^{(m-n)}$ and not the bus impedance matrix $Z_{bus}$. We should use the above four equations (48 - 51) to calculate $Z$, $I_a$, $\Delta V$ and $V'_{bus}$.

3.3 Removal of one line

In most cases, line outage is more common due to fault or over loading. Hence it is more pertinent to study removal of line rather than addition of line. Accommodating removal of line is not at all difficult. Removal of a line $m-n$ with impedance $z_a$ is equivalent to addition of line $m-n$ with impedance $-z_a$.

3.4 Addition / Removal of two lines

The method discussed can be extended to addition or removal of two lines. Let us say we have a power system for which the bus voltages are $V_1', V_2', ..., V_n'$. Two lines of impedance $z_a$ and $z_b$ are added between buses $m-n$ and $p-q$ respectively. It is required to find the new bus voltages $V_1', V_2', ..., V_N'$. The currents in the added lines will be $I_a$ and $I_b$. Then

$$z_a I_a = V_m' - V_n' \quad \text{and} \quad z_b I_b = V_p' - V_q'$$

i.e.
For this case the compensating current is

\[
I_{\text{comp}} = \begin{bmatrix}
0 \\
\vdots \\
-1 \\
0 \\
\vdots \\
-1 \\
0 \\
\vdots \\
0 \\
\end{bmatrix} I = \begin{bmatrix}
-1 \\
0 \\
1 \\
0 \\
\vdots \\
0 \\
0 \\
\vdots \\
0 \\
\end{bmatrix} = A_c \begin{bmatrix} I_a \\ I_b \end{bmatrix}
\]

(53)

Using Superposition Theorem, new bus voltages can be written as

\[
V'_{\text{bus}} = V_{\text{bus}} + Z_{\text{bus}} I_{\text{comp}} = V_{\text{bus}} - Z_{\text{bus}} A_c \begin{bmatrix} I_a \\ I_b \end{bmatrix}
\]

(54)

Using the above equation in equation (51), we get

\[
\begin{bmatrix} z_a & 0 \\ 0 & z_b \end{bmatrix} \begin{bmatrix} I_a \\ I_b \end{bmatrix} = A_c V_{\text{bus}} - A_c Z_{\text{bus}} A_c \begin{bmatrix} I_a \\ I_b \end{bmatrix}
\]

(55)

i.e.
Defining \( Z = Z' + A_e Z_{bus} A_e' \) \hspace{1cm} (57)

The above equation becomes

\[
Z \begin{bmatrix} I_a \\ I_b \end{bmatrix} = \begin{bmatrix} V_m - V_n \\ V_p - V_q \end{bmatrix}
\]

\( \text{i.e.} \)

\[
\begin{bmatrix} I_a \\ I_b \end{bmatrix} = Z^{-1} \begin{bmatrix} V_m - V_n \\ V_p - V_q \end{bmatrix}
\] \hspace{1cm} (58)

Then, the new bus voltages can be written as

\[
V_{bus}' = V_{bus} + \Delta V
\] \hspace{1cm} (59)

Where \( \Delta V = -Z_{bus} A_e' \begin{bmatrix} I_a \\ I_b \end{bmatrix} \) \hspace{1cm} (60)

Thus, new bus voltages \( V_{bus}' \) can be determined as follows:

1) Calculate \( Z \) from equation (57)

2) Calculate \( \begin{bmatrix} I_a \\ I_b \end{bmatrix} \) from equation (58)

3) Calculation \( \Delta V \) from equation (60)

4) Calculation \( V_{bus}' \) from equation (59)

It is noted that equation (57) and (60) contain \( Z_{bus} \), the bus impedance matrix of the system, which is not available. Let us now show that how this problem can be overcome.

**Calculation of \( Z \)**

\[
Z = \begin{bmatrix} z_a & 0 \\ 0 & z_b \end{bmatrix} + \begin{bmatrix} (m-n)[Z_{bus}^{(m-n)}] & (m-n)[Z_{bus}^{(p-q)}] \\ (p-q)[Z_{bus}^{(m-n)}] & (p-q)[Z_{bus}^{(p-q)}] \end{bmatrix}
\] \hspace{1cm} (61)
Calculation of \[ \begin{bmatrix} I_a \\ I_b \end{bmatrix} \]

\[
\begin{bmatrix} I_a \\ I_b \end{bmatrix} = Z^{-1} \begin{bmatrix} V_m - V_n \\ V_p - V_q \end{bmatrix}
\]  
(62)

Calculation of \( \Delta V \)

\[
\Delta V = -Z_{bus} A' \begin{bmatrix} I_a \\ I_b \end{bmatrix}
\] = \[-Z^{(m-n)}_{bus} Z^{(p-o)}_{bus} \begin{bmatrix} I_a \\ I_b \end{bmatrix}\]  
(63)

Calculation of a new bus voltage \( V'_{bus} \)

\[
V'_{bus} = V_{bus} + \Delta V
\]  
(64)

It is to be noted that for the above calculations, we need the vectors \( Z^{(m-n)}_{bus} \) and \( Z^{(p-o)}_{bus} \) only and not the bus impedance matrix \( Z_{bus} \). We should use the above four equations (61-64) to calculate \( Z_{bus} \), \( \Delta V \) and \( V'_{bus} \).

3.5 Half Line Charging Admittance [5]

Consider the diagram below:

![Figure 5](image-url)
Line current from $i \rightarrow j$ is given by

$$I_j = I_i + I_{0i} = y_q(V_i - V_j) + y_{i0}V_i$$  \hspace{1cm} (65)$$

Similarly, the line current $I_j$ measured from bus $j$ to bus $i$ and defined positive in the direction $j \rightarrow i$ is given by

$$I_{ji} = -I_i + I_{j0} = y_q(V_j - V_i) + y_{j0}V_j$$  \hspace{1cm} (66)$$

The complex powers $S_j$ from bus $i$ to $j$ and $S_{ji}$ from bus $j$ to $i$ are

$$S_j = V_i I_j^*$$  \hspace{1cm} (67)$$

$$S_{ji} = V_j I_{ji}^*$$  \hspace{1cm} (68)$$

3.6 Tap Setting for Transformers [5]

Tap changing transformers as well as regulating transformers can be used to control the real and reactive powers. In a tap changing transformer, when the ratio is at the nominal value, the transformer is represented by a series admittance $y_t$ in per unit. With off-nominal ratio, the per unit admittance is different from both sides of the transformer, and the admittance must be modified to include the effect of the off-nominal ratio.

![Figure 6](image-url)

Figure 6

$$\begin{bmatrix} I_i \\ I_j \end{bmatrix} = \begin{bmatrix} y_t & -\frac{y_{i0}}{a} \\ -\frac{y_{j0}}{a} & \frac{y_i}{|a|^2} \end{bmatrix} \begin{bmatrix} V_i \\ V_j \end{bmatrix}$$  \hspace{1cm} (69)$$

For the case where $a$ is real, the $\pi$ model as shown in the figure below represents the admittance matrix above. In the $\pi$ model, the left side corresponds to the non-tap side and right side corresponds to the tap side of the transformers.
3.7 MATLAB Programming

A program is written, based on the factored matrices of bus admittance matrix building algorithm as explained before. The programming is written using MATLAB. The flows of the program are illustrated in the flow chart below:

The line data and initial bus voltages are entered in Microsoft Excel spreadsheet format. Then, the data are imported into MATLAB workspace for further computing.
3.7.1 Program Modules

This program is comprises of several modules, which means it has several functions that working together to achieve the final results. The advantages of writing the program in modular structure are:

1. Each module of function can be run separately, which make it reusable and allow the programmer to work on different modules simultaneously
2. It promotes modularity which can make complex program easier to understand
3. The easiness of doing testing and troubleshooting, when any problem arises

Figure 9: The Program Modules
3.7.2 Creating MS Excel Data File

Before starting the analysis, the line data as well as the pre-outage voltage are to be stored inside the MS Excel. The main purpose for this is, the user will find it much easier to manipulate the data when they are in Excel form, since they can be changed without having to open the MATLAB.

</table>

Figure 10: The IEEE 30 bus line data in MS Excel under "Edata" sheet

Figure 10 illustrate how the line data is written in MS Excel. The pre-outage voltages are to be written, also under the same file name, but different sheet. Please refer to Figure 11 below.
3.7.3 Exporting Excel Data into MATLAB

The line data and the bus voltages can be exported into MATLAB by using a single command. In order to make it more flexible, the user can choose the desired file to conduct the analysis. This is achieved by using the command “uigetfile” in the program. By using this function, it enables the user to select the appropriate data file. The syntax for this function is appended in the appendix.
Then, by using another function "xlsread", MATLAB will read the data in MS Excel and stored them in the workspace in a matrix. Before the matrix can be used for the analysis, it has to be modified slightly, as illustrated in the Figure below.

Figure 12: The matrix

By using the $Y_{bus}$ building algorithm as discussed previously, the $Y_{bus}$ matrix and its factor matrices are constructed. The construction of the matrix also takes the half line charging admittance (HLCA) and tap setting for transformer into consideration. Next, the user will be prompt to input which line to be removed. After the program has obtained all the necessary data required, it will start calculating for the new bus voltages, line currents as well as power flow in each line in the system. The final results are then displayed for clearer view.
3.7.4 Error Handling

In many cases, it is desirable to take specific actions when different kinds of errors occur. For example, the program may want to prompt the user for more input, display extended error or warning information, or repeat a calculation using default values. The error handling capabilities in MATLAB let the program check for particular error conditions and execute appropriate code depending on the situation.

One of the methods used in the program is warning dialog, or `warndlg` in MATLAB. The example of the warning dialog box is illustrated below.

```
Figure 13: The warning dialog
```

"warndlg" displays a dialog box named 'Warning Dialog' containing the string 'This is the default warning string.' The warning dialog box will disappears after you press the "OK" button.

3.7.5 Counter (Stopwatch Timer)

One of the main aspects upon completing this program is to determine what is the program computation time and compare it to the existing approaches (Gauss Seidel, Newton Raphson and Fast Decoupled). Hence, a stopwatch timer has been implemented in this program to calculate how long it will take to complete the calculation.

The counting is started by using command "tic" and ended by command "toc". The program is appended in between of the two, so that the total time elapsed for the program to complete its computation and come to the final results is obtained. The time will be displayed in the Command Window at the end of the calculation. The syntax for these two functions is appended in the Appendix D.
The speed of the computer computation is depends on the speed of the CPU itself. If a fast computer is used, then computation time should be less. On the other hand, if a slower computer is used, the increase in computation time is expected. However, when we compares the computation time between these four methods either by using a faster or slower computer, we should expect the ratio will be the same for both computers.

3.8 Tools

These tools that are used throughout this project are listed below. They are consist if hardware and software.

1) A PC equipped with at least Pentium III or equivalent processor, 128 MB RAM, Microsoft 2000/ME/XP operating system
2) MATLAB software
3) MS Excel (Microsoft Office)

Figure 14: The MATLAB software
CHAPTER 4
RESULTS AND DISCUSSION

The contingency analysis program has been tested on one test system, namely IEEE 30-bus Reliability Test Systems to test its practicality and reliability on real system implementation. The IEEE 30-bus test case represents a portion of American Electric Power System (AEP) in the Midwestern US as of December 1961. It is now being made available to the electric utility industry as a standard case for evaluating various analytical methods and computer programs for the solution of power system problems [8]. The one line diagram of the test case, its bus data and line data is illustrated and appended in the Appendix B.

Before the program is run, the power flow analysis is conducted to get the initial value of the bus voltages on each of the 30 buses. These voltages will be stored in the MS Excel data file, and become the pre-outage bus voltages. Then, one element of the line data is removed or in other words, it is open-circuited. Now, instead of conducting power flow analysis again, the new bus voltages are predicted using the contingency analysis program.

Then, the computation time for the program is determined and then compared with the existing method available. In order to verify the results of the contingency program, its output is compared with the output of the power flow analysis.

4.1 Results and Analysis

The program has been through series of testing of troubleshooting, to ensure the reliability and the accuracy of the results. During one of the testing of the program using IEEE 30 bus system, it is observed that the results are not so accurate, compared to the power flow analysis program. At that time, the line data that are being used are only inclusive impedance and reactance for each line in the power
system. However, it is noticed that they are not sufficient, and therefore the half line charging admittance (HLCA) and the tap setting of the transformers are included in the line data. The effects of these two added elements are discussed earlier in the methodology section.

The Contingency Program will read the line data from MS Excel to construct the bus admittance matrix for the networks. Once the matrix is constructed, it will wait for further instruction. The new line data and the pre-outage bus voltages are appended in the Table 2 and Table 3 below:

4.1.1 Removal of 33\textsuperscript{rd} element (Bus 24 – Bus 25)

When the 33\textsuperscript{rd} element is removed, the new bus voltages are calculated using the Contingency Program and tabulated in the Table 5 below. After the bus voltages are known, the power flows in each line are also calculated and the results can be observed from Table 6.

Then, the results are compared with the results from Power Flow Analysis. As illustrated below, both tables show the comparison between the Contingency Analysis and the Power Flow Analysis results.

\begin{table}[h]

\hline
\end{tabular}
\caption{The initial voltages at each bus after conducting the power flow analysis}
\end{table}
At the same time, the total time elapsed for the program to complete its computation is recorded. The program is run for three times and the average time is taken. Similarly, for the same contingency, three other programs for different methods of power flow are run and the average computation time is taken. The results are illustrated both in Table 4 and Figure 15.

Table 4: Comparison of the computation time (in seconds) between four (4) different methods of power flow, including Contingency Analysis Program in table form

Figure 15: Comparison of the computation time (in seconds) between four (4) different methods of power flow, including Contingency Analysis Program whenever line 24 – 25 was removed. Contingency Analysis program indicates remarkable results in term of its computation time reduction.
From the table and graph above, it is clearly seen that Contingency Analysis gives remarkable reduced computation time compared to the existing methods for Power Flow Analysis. This is really useful and beneficial, when dealing with a much larger system, since it will take less time to complete its computation.

Table 5: The new voltages at each bus when a line 33 is removed

</tbody>
</table>
The percentage of deviation from the Power Flow is calculated by finding the difference between both methods and multiplies it by 100%. This can be done simply because all the units used have been converted to per unit system (P.U.) and 100MVA is used as the system base.

By looking to the deviation of the results of Contingency Program with respect to the Power Flow Program, it can be seen that it does not exceed 10%, which is a good sign. The maximum deviation is 1.38% for real power and -8.72% for reactive power. On the hand, the program can achieve results as accurate as 0.01% for real power and 0% for reactive power. Hence, at this stage it can be concluded that this program can give the closest results to the Power Flow Program.

4.2 Graphical User Interface

Programming for integrating Graphical User Interface with the MATLAB program is complete but it does not stop there. It will be keep improving from time to time, as the technology changes.
The main page of the program consists of three sections, namely HOME, LINE OUTAGE and OVERLOAD RELIEF. Each has its own functions. To start with the analysis, click the LINE OUTAGE button. Then, the "CONTINGENCY ANALYSIS" section will be displayed as illustrated in the Figure 17 below.

![Figure 17: The Single Contingency Section](image)

Next, the data file is selected properly so that the program will read them. The element number to be removed is entered in the box by clicking LOCATION button. After clicking OK and CALCULATE button and the program will start calculating the power flow in each line. Please refer Figure 18 and Figure 19.
Figure 18: Select the correct data

Figure 19: Enter the input and click CALCULATE!
In order to see the results, click on the View Results! button, and another window will appear. This is actually the one-line diagram of the IEEE 30 bus system. Consequently, by clicking Update! button within the window, the power flow on each line in the networks can be seen clearly. The displayed results can be removed just by clicking the Clear! button.

Figure 20: The displayed results
CHAPTER 5
CONCLUSION AND RECOMMENDATION

An alternative way of doing power flow analysis when possible line outage occurs has been presented in this project. Methods of contingency analysis which used the factored Bus Admittance Matrix $Y_{bus}$ becomes attractive from computational viewpoint, especially if the loads can be treated as constant current injections into the various buses of the system. Even though the program does not give results as accurate as power flow, it is not so much important because the system planners and operators, who must undertake hundreds of studies in a short time period, are more concerned with knowing if overload levels of current and out-of-limit voltages and power flow exist than with finding the exact values of those quantities.

This Contingency Analysis program has been tested on an IEEE 30 buses Test System to test its effectiveness, practicality and reliability. From the results and findings, it is can be concluded that this program exhibits remarkable advantage in term of its computation time reduction, as well as its accuracy to the exact solution.

Undoubtedly, it is a big advantage for conducting this analysis on a large system. The computation time will be reduced significantly and therefore this will benefits the electrical utility company itself.

It is therefore important to suggest some improvements and recommendations for the benefit of the project. Since this area is growing, there are opportunities for this approach to be widely applied in the power system engineering. The existing system can be integrated with another system that control the generation of power, in which the effects of both line outage and the power generation control, can be exhibited by the program. If that can be done, this program will be a great success.

APPENDIX D – MATLAB Functions syntax

uigetfile
Open standard dialog box for retrieving files

Syntax

```
uigetfile
uigetfile('FilterSpec')
uigetfile('FilterSpec','DialogTitle')
uigetfile('FilterSpec','DialogTitle','DefaultName')
uigetfile(...,'Location',[x y])
uigetfile(...,'MultiSelect',selectmode)
[FileName,PathName] = uigetfile(...)  
[FileName,PathName,Filterlndex] = uigetfile(...)  
```

xlsread
Read Microsoft Excel spreadsheet file (.xls)

Syntax

```
um = xlsread(filename)
um = xlsread(filename, -1)
um = xlsread(filename, sheet)
um = xlsread(filename, 'range') 
um = xlsread(filename, sheet, 'range') 
um = xlsread(filename, sheet, 'range', 'basic') 
um = xlsread(filename, ..., functionhandle)  
[num, txt]= xlsread(filename, ...)  
[num, txt, raw] = xlsread(filename, ...)  
[num, txt, raw, X] = xlsread(filename, ..., functionhandle)  
xlsread filename sheet range basic
```

warndlg
Open warning dialog box

Syntax

```
warndlg('warningstring')
warndlg('warningstring', 'dlgname')
h = warndlg('warningstring', 'dlgname', createmode)
h = warndlg(...)  
```

tic, toc
Measure performance using stopwatch timer

Synopsis

```
tic
    any statements
toc
t = toc
```
