# CERTIFICATION OF APPROVAL 

# REDUCTION OF LOSSES IN RADIAL DISTRIBUTION LINES USING FUZZY LOGIC 

by<br>Mohd Fariz bin Daud

A project dissertation submitted to the Electrical \& Electronics Engineering Programme

Universiti Teknologi PETRONAS in partial fulfilment of the requirement for the

Bachelor of Engineering (Hons)
(Electrical \& Electronics Engineering)

Ir. Perumal Nallagownden
Project Supervisor

## CERTIFICATION OF ORIGINALITY

This is to certify that I am responsible for the work submitted in this project, that the original work is my own except as specified in the references and acknowledgements, and that the original work contained herein have not been undertaken or done by unspecified sources or persons.

#### Abstract

Distribution system provides the final link between the high voltage transmission system and the customers. Radial distribution system with a single circuit main feeder is popular because of simple design and generally low cost. The power loss in a distribution system is significantly high because of lower voltage hence high current and losses $\left(I^{2} R\right)$. Reduction of reactive power is beneficial to improve overall efficiency and reduce cost. This project is to analyze losses in radial distribution system and compensate the losses with an intelligent method using fuzzy logic. Fuzzy logic is used together with numerical approach to determine the suitable candidate node for capacitor placement at distribution load busbar to compensate losses in the line. This report will articulate the work that has been done by the author in the project for the purpose of fulfillment of the Final Year Project.

## ACKNOWLEDGEMENTS

Firstly, the author would like to express sincere gratitude to his supervisor, Ir. Perumal Nallagownden for all the support and guidance given throughout the period of this project. His experience and knowledge has helped a lot in making this project as it is now.

The author would also further the appreciation to Mr. Zuhairi Baharudin, Ir. Thum Peng Chew and technicians, Mr. Yasin and Ms. Siti Hawa for all the guidance and cooperation given. Not forgetting all the colleagues who had been helpful in many aspects throughout the project.

In the process of conducting the project, the author has faced difficulties and sometimes becomes uninspired. Thousand thanks again for those who helped a lot in motivating and encouraging the author in finishing the project, who inspires the author directly or indirectly.

Last but not least, the author would also like to acknowledge Ms. Nasreen Badruddin and Mr. Mohd. Zuki Yusoff, the EE Final Year Project Coordinators, for all the guidance given in realizing and fulfilling the objectives of the project.

## CHAPTER 1 <br> INTRODUCTION

This chapter illustrates the introduction part of the project. Introduction will consists of background study, problem statement, objectives and scope of study.

### 1.1 Background of Study

Cost and effectiveness are the main criteria in designing a power distribution system to the consumers. In a distribution system, power loss is a major issue in delivering the service. Loss due to active component of current cannot be minimized because all active power must be supplied by the source. However, loss due to reactive component of current can be reduced by supplying part of the reactive power demand locally.

There are several solutions to serve the purpose of compensating the reactive power. One of the methods is installing shunt capacitors in a distribution system to reduce the reactive power losses. This project involve of reviewing the existing shunt capacitor placement method and introducing fuzzy logic method to determine the suitable candidate nodes in a distribution system for capacitor placement.

### 1.2 Problem Statement

Distribution network is the intermediate network between the transmission system and the consumers. The problems that may be found in the distribution network affect both the consumers and utilities especially in the industries. One of these problems is the problem of voltage drop that must be reduced to keep the voltage at loads points within standard limits. The voltage drop may arise when using lateral radial feeders with long distance or feeding large loads i.e. in industries where power is needed for inductive loads such as motors, compressor or ballast to generate and sustain a magnetic field in order to operate.

That kind of power to be compensated is the reactive power which is also known as non-working power. Reactive power is always associated with power factor. Higher loss of reactive power leads to low power factor. In other words, reduction of reactive power has the same meaning with improvement of power factor and reduction of reactive power can reduce the total power.

### 1.3 Objectives and Scope of Study

### 1.3.1 Objectives

The main objective of this project is to study on the compensation of reactive power in the radial distribution system and to come out with an intelligent method to compensate the losses. For this project, the fundamental objectives are:

- To conduct a study on the radial distribution system
- To conduct a study and understand the concept of reactive power and losses
- To review and identify the techniques available for reactive power compensation
- To come out with an effective method for the loss reduction
- To evaluate the performance of the applicable technique and compare the result with other methods

After the appropriate method is reviewed, it will be adopted in this loss reduction process. The result obtained will be compared with results from previous works using other methods.

### 1.3.2 Scope of Study

The scope of study is mainly on the distribution network - regarding the losses, method to find the node with highest loss, compensation of the losses and method to find the solution of the best approach for loss reduction. This project uses fuzzy logic methods or approach as a technique to find the best solution for reactive power compensation. The later part of this project concentrates on applying fuzzy logic technique in radial distribution system for the purpose of reducing the losses.

## CHAPTER 2 <br> LITERATURE REVIEW AND THEORY

### 2.1 Overview on Distribution System

Basically a complete electric power consists of generation, transmission and distribution [12]. Distribution is the part that connects the high voltage transmission network to the low voltage consumer service point. It consists of distribution substation which converts transmission voltages ranges from 11 kV or 33 kV to distribution voltages of 240 V for single phase or 415 V for three phase.

### 2.1.1 Radial Distribution System

Radial distribution system is a system which the power distributor connects to the supply at one end only. Through this type of distribution system, the end of the distributor nearest to the generating station would be heavily loaded. The advantage of this configuration is lower cost of implementation. However, the disadvantage is that, when the nearest distributor has power interruption, it will affect the entire network. Most of the network configuration in Malaysia uses this system.

### 2.2 Reactive Power Losses in Distribution System

Reactive power is non-working power in KVAR unit where its amount in one direction is equal to the one flowing in the opposite direction [12]. Average reactive power in a system is zero. Reactive power is associated with power factor. The relationship between active, reactive and apparent power can be seen from the power triangle.

Figure 1 Power Triangle

$$
\begin{aligned}
& \text { PowerFactor }=\frac{\text { ActivePower, } P}{\text { ApparentPower, } S}=\cos \theta=\frac{K W}{K V A} \\
& \text { ApparentPower, } S=\text { ActivePower, } P+\operatorname{Re} \text { activePower, } Q
\end{aligned}
$$

Reactive power is associated with power factor. Higher loss of reactive power leads to low power factor which is inefficient and expensive. Compensation [7][4] of reactive power means improvement of power factor and efficiency of the system.

There are generally many factors contribute to losses in distribution system. Among them are:
i. Long distribution distance which resulted in high line resistance and reactance, low voltage and high current that leads to high losses.
ii. Low power factor contributes towards high distribution losses.
iii. Location of distribution transformers - the farthest customers from the distribution transformers obtain an extremely low voltage even though a reasonably good voltage level is maintained at the transformer secondary.

The total power loss $\left(P_{L}\right)$ in a distribution system having $b$ number of branches is given by [7]:

$$
\begin{equation*}
P_{L}=\sum_{i=1}^{b} I_{i}^{2} R_{i} \tag{2.1}
\end{equation*}
$$

Here $I_{i}$ and $R_{i}$ are the current magnitude and resistance respectively, of the $i$-th branch. The branch current can be obtained from the load flow analysis. The branch current has two components; active $\left(I_{a}\right)$ and reactive $\left(I_{r}\right)$. The loss associated with the active and reactive components of branch currents can be written as:

$$
\begin{equation*}
P_{L a}=\sum_{i=1}^{b} I_{a i}^{2} R_{i} \tag{2.2}
\end{equation*}
$$

$$
\begin{equation*}
P_{L r}=\sum_{i=1}^{b} I_{r i}^{2} R_{i} \tag{2.3}
\end{equation*}
$$

Note that, for a given configuration of a single source radial network, the loss $P_{L a}$ associated with the active component of branches cannot be minimized because all active power must be supplied by the source at the root bus. However, supplying a part of the reactive power demand locally by using capacitors of optimal size can minimize the loss $P_{L r}$ associated with the reactive component of branch currents.

### 2.2.1 Techniques to Reduce Reactive Losses

The most popular technique for compensating reactive power losses is using capacitors. Shunt capacitor compensation is the most popular method used since it is efficient and cost effective. Capacitors supply an amount of reactive power to the system at the point where they are connected [1]. Suitable capacitor banks at grid or main substation are desirable to compensate reactive power of lines [10].

According to Salama[4], there is a method of minimizing the lost of reactive power by placing optimal capacitors at proper location. The method first finds the location of the capacitor in sequential manner. Once the capacitor locations are identified, the size of optimal capacitor at each selected location is determined through optimizing the loss saving equation. According to the results, the busses as well as the corresponding optimal capacitors are determined in such a way that maximum loss reduction is achieved with minimum capacitor installment.

### 2.3 Load Flow Analysis [1]

Let us consider the IEEE 34-bus test system. In this method, the initial values of node voltages are assumed to be $(1+\mathrm{j} 0)$ p.u. the load current at each node can be formed from the relation;

$$
\begin{align*}
& J_{i}=\frac{P_{i}-j Q_{i}}{V_{i}^{*}}+\frac{V_{i}}{Z_{i}}+Y_{i} V_{i}+I_{L i}  \tag{2.4}\\
& i=1,2 \ldots n b
\end{align*}
$$

Where $n b \rightarrow$ no. of nodes or buses

The branch currents can be written in terms of load currents of all nodes and simplified in matrix form as:

$$
\begin{equation*}
\left[I_{b}\right]=[C]\left[J_{L}\right] \tag{2.5}
\end{equation*}
$$

Where $\mathrm{C} \rightarrow$ branch to node matrix of kxk matrix

$$
\mathrm{J}_{\mathrm{L}} \rightarrow \text { Load current }
$$

The voltage drops across all branches can be computed from the relation:

$$
\begin{equation*}
\left[V_{b}\right]=[Z] \cdot\left[I_{b}\right] \tag{2.6}
\end{equation*}
$$

Where $I_{b} \rightarrow$ Branch current

The node voltages can be written in terms of branch voltages:

$$
\begin{align*}
& V_{i}=V_{o}-\sum_{j=1}^{b} C_{j i} V_{j}  \tag{2.7}\\
& \mathrm{i}=1,2, \ldots \mathrm{n} \\
& \text { Where } \mathrm{b} \rightarrow \text { number of branches }
\end{align*}
$$

The branch-to-node matrix, $[\mathrm{C}]$ is formed from the topology description of the given system (34-bus test system). The load currents, branch currents, branch voltages and node voltages are computed successively for a given set of load data and source node voltage, using previous equations, respectively by iteration process. The convergence is obtained when the difference between node voltages of two successive iterations is less than the specified values.

### 2.4 Loss Minimization by a Singly Located Capacitor [7][1]

Consider a single source radial distribution system with $b$ branches and $n b$ nodes. Let a capacitor $C$ be placed at bus $m$ and $\alpha$ be a set of branches connected between the source and the capacitor buses. If the capacitor is placed at bus $12(m=12)$, the set $\alpha$ : consists of branches $1,2,3,4,5,6,7,8,9,10$ and 11 . The capacitor draws a reactive current $I_{c}$ and for a radial network, it changes only the reactive component of current of branch set $\alpha$.

The current of other branches $(\nexists \alpha)$ is unaffected by the capacitor. Thus the new reactive current $\mathrm{I}_{\mathrm{ri}}{ }^{\text {new }}$ of the $i$-th branch is given by:

$$
\begin{aligned}
& I_{r i}^{\text {new }}=I_{r i}+D_{i} I_{c} \\
& \text { Where } \mathrm{D}_{\mathrm{i}}=1 ; \text { if branch } I \propto \alpha \\
& =0 ; \text { otherwise }
\end{aligned}
$$

Here $I^{t i}$ is the reactive current of the $i^{\text {th }}$ branch in the original system obtained from the load flow solution. The loss $P_{L r}{ }^{C o m}$ associated with the reactive component of branch current in the compensated system (when the capacitor is connected) can be written as:

$$
\begin{equation*}
P_{L r}^{C u m}=\sum_{i=1}^{b}\left(I_{r i}+D_{i} I_{c}\right)^{2} R_{i} \tag{2.9}
\end{equation*}
$$

The loss saving $S$ is the difference between eqn. (2.3) and (2.9) is given by:

$$
\begin{equation*}
S=P_{L r}-P_{L r}^{C o m}=-\sum_{i=1}^{b}\left(2 D_{i} I_{n i} I_{c}+D_{i} I_{c}^{2}\right) R_{i} \tag{2.10}
\end{equation*}
$$

The capacitor current $\mathrm{I}_{\mathrm{c}}$ that provides the maximum loss saving can be obtained from:

$$
\begin{equation*}
\frac{\partial S}{\partial I_{c}}=-2 \sum_{i=1}^{b}\left(D_{i} I_{r i}+D_{i} I_{c}\right) R_{i}=0 \tag{2.11}
\end{equation*}
$$

The capacitor current for the maximum loss saving is:

$$
\begin{align*}
& P_{L r}^{C u m}=\sum_{i=1}^{b}\left(I_{r i}+D_{i} I_{c}\right)^{2} R_{i} \\
& I_{c}=-\frac{\sum_{i=1}^{b} D_{i} I_{r i} R_{i}}{\sum_{i=1}^{b} D_{i} R_{i}}=-\frac{\sum_{i \in \alpha} I_{r i} R_{i}}{\sum_{i \in \alpha} R_{i}} \tag{2.12}
\end{align*}
$$

The corresponding capacitor size is:

$$
\begin{equation*}
Q_{c}=V_{m} I_{c} \tag{2.13}
\end{equation*}
$$

Here $V_{m}$ is the voltage magnitude of the capacitor bus $m$ where this capacitor is to be connected.

### 2.5 Fuzzy Logic System

### 2.5.1 Fuzzy Sets

Fuzzy Logic starts with the concept of a fuzzy set [3]. A fuzzy set is a set without a crisp, clearly defined boundary. It can contain elements with only a partial degree of membership. The fuzzy set is essentially a generalization of the classical or ordinary set. The ordinary set is defined in such a way that individuals in some given universe of discourse are divided into two groups: members - those that certainly belong in the set and non-members - those that certainly do not.

A sharp ambiguous distinction exists between the members and non-members of the class or category represented by the ordinary set. However, many of the categories commonly employed to describe our perception of reality do not exhibit this sharp distinction. For example, there is no sharp distinction in classifying between a level of height of a student: TALL or SHORT. Most would agree that a height of 1.80 meters is TALL and 1.20 meters is short, but what if the height is 1.55 meters? It seems like it is a part of TALL, but somehow it appears like it should be excluded. Classical sets would not tolerate this kind of thing. It will interpret either TALL or SHORT only. The fuzzy sets introduce vagueness by eliminating the sharp boundaries dividing members of the class from non-members. In fuzzy logic, the truth of any statement becomes a matter of degree.

### 2.5.2 Fuzzy Membership Functions [4]

A membership function (MF) is a curve that defines how each point in the input space is mapped to a membership value (or degree of membership) between 0 and 1 . The input space is sometimes referred to as the universe of discourse.

Mathematically, a fuzzy set is defined by assigning to each individual in the universe of discourse a value in the interval $[0,1]$ representing its degree of membership in the fuzzy set, depending on its similarity to the concept represented by the fuzzy sets. Thus, an individual may reside in a fuzzy set of a certain degree (greater or lesser) membership functions from range of 0 to 1 .

### 2.5.3 Fuzzy Logical Operations

The three basic operations [8] on fuzzy sets are: complement, union and intersection. The basic operations are defined as functions that satisfy certain axiomatic requirements and operate on membership grades of fuzzy sets. The results of these operations are membership functions of new fuzzy sets representing the concept of fuzzy complement, union and intersection.

## 1. NOT (Complement)

NOT is the complement operator. The membership function NOT Tall is described by the equation:

$$
\begin{equation*}
\mu_{\text {NoTrall }}(x)=1-\mu_{\text {Tal }}(x) \tag{2.14}
\end{equation*}
$$

Complementation of fuzzy sets also has the property that

$$
\begin{equation*}
\mu_{\text {NotNotrall }}(x)=1-\mu_{\text {Norrail }}(x)=\mu_{\text {Tall }}(x) \tag{2.15}
\end{equation*}
$$

2. $A N D$ (Intersection)

AND is the intersection operator. The AND operator requires at least two arguments. With fuzzy logic, those arguments are membership functions (MF). Using the intersection operator, the mathematical notation for the intersection of the Tall and Short fuzzy sets is:

$$
\begin{equation*}
\mu_{\text {Tall Shorr }}(x)=\min \left[\mu_{\text {Tall }}(x), \mu_{\text {Shorl }}(x)\right] \tag{2.16}
\end{equation*}
$$

This equation describes the intersection of Tall and Short as the pointwise minimum of two fuzzy sets.
3. $O R$ (Union)

OR is the union operator. The OR operator also requires at least two arguments. Using the union operator, the mathematical notation for the union of the Tall and Short fuzzy sets is:

$$
\begin{equation*}
\mu_{\text {Tall YShori }}(x)=\max \left[\mu_{\text {Tall }}(x), \mu_{\text {Shorl }}(x)\right] \tag{2.17}
\end{equation*}
$$

### 2.5.4 Fuzzy IF-THEN Rule

Fuzzy sets and fuzzy operators are the basic component of fuzzy logic. These IFTHEN rule statements are used to formulate the conditional statements that include Fuzzy Logic. A single fuzzy IF-THEN rule [3][8] assumes the form:

$$
\text { IF x is } A \text { THEN y is B }
$$

Where A and B are linguistic values defined by fuzzy sets on the ranges (universe of discourse) X and Y , respectively. The IF part of the rule " $x$ is $A$ " is called the antecedent or premise, while the THEN part of the rule " $y$ is $B$ " is called the consequent or conclusion.

Interpreting the IF-THEN rules is a three part process. The first part is the fuzzification of input. This part resolves all fuzzy statements in the antecedent to a degree of membership between 0 and 1 . If there is only one part to the antecedent, this is the degree of support for the rule. The second part is to apply fuzzy operator to multiple part antecedents. If there are multiple parts to the antecedent, fuzzy logic operators are applied and the antecedent is resolved to a single number between zero and one. This is the degree of support for the rule.

The last part is to apply the implication method. The degree of support for the entire rule is used to shape the output fuzzy set. The consequent of a fuzzy rule assigns an entire fuzzy set to the output. This fuzzy set is represented by a membership function that is chosen to indicate the qualities of the consequent.

## CHAPTER 3

## METHODOLOGY

This chapter describes the methodology used in completing this project. It consists of the identification of procedures as well as tools required for the entire project.

### 3.1 Procedure Identification

Gantt chart in Appendix A an B shows the milestone in completing this project for the two-semesters final year project also the task completed by the author.

The research began with literature review of electrical power and basic distribution system. The study continued with theories on losses specifically on reactive losses in radial distribution system. Afterwards, techniques of compensating the losses of reactive power were reviewed and evaluated. The task done after that is the simulation/implementation of the techniques using appropriate software/simulation system.

For the project work, fuzzy logic technique is going to be evaluated. Through fuzzy logic, the best locations of busbars for capacitor placement will be decided. The sizes of the capacitors to be placed are then calculated. From the value obtained, shunt capacitors will be placed onto the selected busbars. The placement of the capacitors will be simulated using load flow analysis software. With the proposed method, the final result obtained would be compared to the project done previously using different technique. Figure 2 shows the flow of this project.

Figure 2 Methodology Flow Chart

### 3.2 Tools Required

The tools and software required for this project would be simulation software and test system for the simulation of the actual distribution system. The software is used for simulating and calculating the voltage and current of respective buses by means of load flow analysis.

### 3.2.1 MATLAB

For the calculation algorithm, MATLAB is to be used. MATLAB is an interactive software system for numerical computations and graphics. MATLAB is used as the calculation involves matrix computation for algorithm designing and simulations especially for fuzzy logic. Programming in MATLAB is more convenient compared to other similar programming software since declaration is not required and has its own module for fuzzy logic programming and simulation (Fuzzy Toolbox).

### 3.2.2 ERACS Power System Analysis Software

ERACS is a powerful and useful software used for power system analysis of the project. It has all the main elements that are available in a power system. This software is used for load flow analysis for simulation purpose.

### 3.2.3 IEEE 34-bus Test System

For simulation of the system, a standard test model is needed. This model should represent the actual radial distribution system. Simulation is done on this test system and from result of simulation, the new approach is determined whether suitable or not to be implemented on a real practical system. If there is no problem with simulation, there should be no problem in applying the system practically. The IEEE 34-bus standard test system will be used as the test model for this project.

Figure 3 Single Line Equivalent of IEEE 34-bus Test System

## CHAPTER 4

## PROJECT WORK

Before applying fuzzy logic technique, a load flow analysis need to be done to calculate the distribution losses in the system. From the load analysis obtained, fuzzy logic is to be applied to locate the appropriate location for capacitor placement for optimum loss reduction. Some assumptions are made:

1. The load real and reactive power on the node of the feeders are known
2. The feeders are 3 -phase and are balanced
3. Harmonic current are disregarded

### 4.1 Load Flow Analysis

From the load flow analysis using ERACS software on the IEEE 34-bus test system, parameters such as bus voltage and line current will be obtained. Line current is needed to calculate the losses (real and reactive loss). Losses exist in the line/branch since there resistance and voltage difference between the corresponding buses.

The network of 34 -bus test system is constructed using ERACS. A diagram of network is attached in the Appendix E.

### 4.2 Proposed Method

For single capacitor placement method, a shunt capacitor is placed at the suitable busbar. Then the simulation is run once again with the first capacitor installed to find the next suitable candidate node for capacitor placement. The process is conducted several times until the loss saving is no longer significant (loss saving less than 1 $k W$ ). Flowchart below illustrates the entire process for single shunt capacitor placement.

Figure 4 Flowchart of the proposed method

IEEE 34-bust test system is used as a test system for this project to represent the actual radial distribution line. All the line and load data of the test system will be put into ERACS (power analysis software) to be simulated. After all values have been inserted, load flow of the system is conducted, where the result will be used in the next step.

From the load-flow analysis result, data of voltage profile $(V)$, line current $(I)$ and current angle will be used. These data are then evaluated to obtain the current of reactive part $\left(I_{r}\right)$ and the power losses of the reactive part $\left(P_{r}\right)$. Fuzzy Logic will be used based on these set of data.

A MATLAB program is designed to take the inputs of loss of the reactive part $\left(P_{r}\right)$, voltage ( $V_{p u}$ ) and reactive current $\left(I_{r}\right)$. These inputs will be triggered into the Fuzzy Logic system that has been developed previously and integrated into the program. Once the program is loaded, it will immediately give the output of bus number with the highest suitability and at same time calculate the capacitor size to be compensated. Both the bus number and the capacitor size will be displayed.

Using the bus number and capacitor size obtained, the 34-bus test system data (using ERACS) for the load flow analysis is modified by placing the shunt capacitor. Then, load flow analysis is run once again with the shunt capacitor installed. From the result of the load flow, a new set of voltage profile, reactive power loss and total power loss will be obtained. The result will be tabulated and compared to the values before compensation and the power loss saving will be noted.

Using the new values of $P_{r}, V_{p u}$ and $I_{r}$, the program is run again to obtain the next suitable busbar for capacitor placement also the new capacitor size.

The above steps are repeated several times until the lost saving obtained is not less than 1 kW . The final result will be tabulated and the total loss saving is noted. Finally graphs will be plotted to visually see the difference of the losses and also the voltage profile, before and after the capacitors placement.

### 4.2.1 Fuzzy Logic System

Fuzzy Logic is used as a method to find the suitable busbar for shunt capacitor placement. For the fuzzy logic part, the Fuzzy Logic toolbox inside MATLAB is used. Fuzzy Logic Toolbox is selected instead of FuzzyTech software because it is more convenient to be integrated with calculation part with MATLAB. Flowchart
below illustrates the steps in creating the fuzzy logic system for finding the suitable busbar for compensation.

Figure 5 Steps for creating fuzzy logic system

A concern for the development of fuzzy systems is the assignment of appropriate membership functions. Constructions of membership functions can be based on intuition, rank ordering or probabilistic method. The most commonly used membership functions is the triangular shaped.

There Fuzzy Logic system basically consists of 3 parts, which are the inputs, inference rules and output. Figure below shows the relationship between the antecedents (inputs) and consequence (output)

Figure 6 Fuzzy Logic System

## Inputs:

The variables to the Fuzzy Logic system are Loss of Reactive Part $\left(P_{r}\right)$ and Voltage ( $V_{p u}$ ), whereby these values are to be compensated later. These values are taken from the evaluation of result from the load flow analysis.

From the result of the load flow, the membership function of the input variables is defined. For $\boldsymbol{P}_{r}$, five membership functions are formed, namely low, lowmed, med, himed and high. Triangular membership functions are commonly used. The width of each membership functions depends on how it is defined based on the $P_{r}$ data from load flow analysis. Note from the figure below that reactive part loss, $P_{r}$ from 6 to 10 kVAR is considered high, 3 to 6 is considered medium and 0 to 2 is considered low in losses.

Figure 7 MF of input variable, $\operatorname{Pr}$

Another input variable of the fuzzy logic system is the voltage, $V$. This information is also taken from the load flow analysis data of voltage in pu $\left(V_{p u}\right)$. And the width of each membership functions is also defined according to the author's logical decision based on tabulation of the data. Voltage from 0.99 to 1 V p.u is considered high; where else other membership functions of hinorm, normal, lonorm and low can be viewed in figure below.

Figure 8 MF of input variable, V

## Output:

Next step is to define the output variable which is the capacitor placement suitability, $S$. The capacitor placement suitability is normalized from 0 to 1 , where the busbar with highest suitability will be selected to be compensated with shunt capacitor. The output variable, $S$ consists of 3 membership functions namely low, med and high. The membership functions are uniformly distributed. Less membership functions are used for the purpose of reducing the processing time while obtaining similar result (See figure below).

Figure 9 MF of output variable, S

## Inference rules:

When losses and voltage level of a distribution system are studied, an experienced engineer can choose locations for capacitor placement which are probably highly suitable. For example, it is intuitive that a section with high losses and low voltage is highly ideal for placements of capacitors; whereas a low loss section with good voltage is not.

This part is to define the relationship between inputs and output and how the inputs will influence the output. The rules are defined based on condition - IF reactive part loss HIGH and voltage LOW, THEN capacitor placement suitability is HIGH. From there, a set of inference rules is developed with the help of the writer's logical decision making process. The rule base can be summarized in the table below. The full set of inference rules obtained from the table is attached in the Appendix C. Those rules are inserted one by one into the rule block of the fuzzy logic system.

Table 1 Rules for capacitor placement suitability output

| AND |  | Voltage |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Low- <br> Normal | Normal | High- <br> normal | High |  |

|  | Low-Med | Low | Low | Low | Low | Low |
|  | High-Med | Med | High | Med | Med | Low |
|  | High | High | High | Med | Med | Mow |

## CHAPTER 5

## RESULT AND DISCUSSION

### 5.1 Load Flow Analysis Data

Load flow analysis is the first step in determining the loss of the system. Then the fuzzy logic method can be applied to find the suitable bus for loss compensation. From load flow analysis, the voltage profile (in kV and p.u.) and the line current (in kA ) is obtained. The voltage profile and the corresponding bus numbers are tabulated in Table 2.

The line current has two components, which are the active and reactive components. This component has already been discussed earlier in the theory part. Basically, the loss associated with the active component can only be minimized by the source at the generator bus. The loss associated with reactive component however, can be reduced by supplying part of the reactive power locally by means of shunt capacitors.

Table 3 shows the active current and angle, also the calculation for the reactive current. The loss due to active and reactive part is also calculated and the sum of these two losses gives the total real losses.

### 5.2 Single Capacitor Placement

From the data of load flow analysis in Table 3, the loss of reactive part $\left(P_{r}\right)$, bus voltages $\left(V_{p u}\right)$ and current of reactive part $\left(I_{r}\right)$ are inserted into the MATLAB program (which integrates the Fuzzy Logic and an algorithm to calculate the capacitor size) to obtain the capacitor placement suitability (refer to Appendix D). The MATLAB program is run and immediately the bus number with highest suitability will be obtained, together with the capacitor size to be compensated.

For the first iteration, Bus 6 is found to be the suitable node for placement with capacitor size of $\mathbf{1 1 4 8 . 6 0} \mathbf{~ k V A R}$.

```
The most suitable bus for capacitor placement is bus }
and the capacitor size is 1148.6 kVAR
```

Figure 10 Output of MATLAB for $1^{\text {st }}$ iteration

Once the bus number and capacitor size is obtained, the corresponding bus data in the 34-bust test network is updated. Then ERACS is run one more time to obtain the load flow of the new system with one capacitor installed. The same procedure as above, where the new $P_{r}, V_{p u}$ and $I_{r}$ in inserted into the MATLAB program to obtain the next suitable bus number for capacitor placement. These procedures are repeated several times until 5 capacitors are placed onto the network to compensate the losses.

After 5 iterations, 5 capacitors are installed onto the network on bus $6,17,18,19$ and 21. Table 4 below summarized the bus numbers and their respective capacitor size.

Table 4 Bus number and capacitor size

| Iteration | Bus | Capacitor Size |
| :---: | :---: | :---: |
| 1 | 6 | 1148.60 |
| 2 | 17 | 823.45 |
| 3 | 18 | 481.41 |
| 4 | 19 | 306.85 |
| 5 | 21 | 239.72 |

After all the capacitors are placed on the designated buses, the load flow analysis is run once again to obtain the new load flow and the loss saving of the system. Table 5 summarized the load flow data after all capacitors are in place.

| 31 | 0.011 | -31.54 | -0.00570 | 0.20960 | 0.02044 | 0.00929 | 0.05427 | 0.07471 |
| 32 | 0.007 | -31.54 | -0.00377 | 0.15720 | 0.00669 | 0.00614 | 0.01776 | 0.02445 |
| 33 | 0.004 | -31.54 | -0.00188 | 0.10480 | 0.00111 | 0.00307 | 0.00296 | 0.00407 |
|  |  |  |  | TOTAL | 11.99863 |  | 158.38965 | 170.38829 |

From the load flow analysis of the $5^{\text {th }}$ iteration, the total power loss can be calculated and power saving of the system can be found. The total power loss and total saving is tabulated below.

Table 6 Losses and savings

| No. of Capacitors | Total Real Power Loss | Power Loss Saving | Total Saving |
| :---: | :---: | :---: | :---: |
| 0 | 221.72 |  |  |
| 1 | 193.08 | 28.64 | 28.64 |
| 2 | 179.28 | 13.80 | 42.44 |
| 3 | 174.37 | 4.91 | 47.35 |
| 4 | 172.21 | 2.16 | 49.51 |
| 5 | 170.39 | 1.82 | 51.33 |

From the tabulated result, it can be observed that the total power loss is reduced after compensation and the total power saving is $\mathbf{5 1 . 3 3} \mathbf{~ k W}$.

By placing shunt capacitors, the voltage profile of the network will also be improved. This is because the current flowing in the line is decreasing due to flow of less reactive component branch current that reduces the voltage drop, hence improve the voltage profile. Table 7 below shows the comparison between voltage profile before and after the capacitor placement. Note that voltage profile at every bus is improved.

Table 7 Voltage profile before and after capacitor placement

| Busbar | Voltage |  |
| :---: | :---: | :---: |

For comparison, Figure 11 below shows the comparison of power losses of reactive part in the system before and after the capacitors placements. The fuzzy logic system considers the loss reduction and the voltage profile simultaneously when deciding which nodes are most ideal for capacitor placement. Hence, a good compromise of loss reduction and voltage profile improvement is achieved. In Figure 12, the improvement of the voltage profile before and after compensation of capacitors can be observed.

Voltage Profile after Compensation

### 5.3 Comparison with Existing Method

Results obtained from the simulation would be compared to an existing method using heuristic search strategies by M Chis, M.M.A Salama and Jayaram[6]. Table below shows the comparison between the results of two methods. As seen from the table, the proposed method using fuzzy logic compensates losses up to 51.33 kW with 3000.08 kVAR capacitors bank while the existing method compensates 53.69 kW with 2700 kVAR capacitors bank.

Table 8 Result Comparison

| Iteration | Bus No. |  | Capacitor size (kVAR) |  | Saving (kW) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| No. | Proposed Method | Method (1) | Proposed Method | Method (1) | Proposed Method | Method (1) |
| 1 | 2 | 26 | 1148.6 | 1400 | 28.64 | 41.07 |
| 2 | 4 | 11 | 823.45 | 750 | 13.8 | 10.64 |
| 3 | 6 | 17 | 481.41 | 300 | 4.91 | 1.17 |
| 4 | 7 | 4 | 306.85 | 250 | 2.16 | 0.81 |
| 5 | 8 | Wix | 239.77 |  | 1.82 |  |
|  |  | TOTAL | 3000.08 | 2700 | 51.33 | 53.69 |

Although the saving offered by the proposed system is less, it is more realistic to be applied in actual system, since the losses used by this system are not calculated based on appropriate formulas, but from the load flow. Thus this fuzzy system approach will choose a more reliable location for capacitor placements. In addition to the above advantage, the simplicity and the flexibility of using the fuzzy system are apparent. The system requires only the losses and voltages of the feeder sections to determine the suitable locations for capacitor placement.

## CHAPTER 6

## CONCLUSION

As for the conclusion, loss reduction for radial distribution network using fuzzy logic is implemented in this project. Fuzzy Logic is used as a tool to find the suitable bus for capacitor placement. ERACS power system analysis software is used as simulation tool for load flow analysis. For the purpose of calculating the capacitor size and integrating with fuzzy logic, MATLAB is used whereby it has its own Fuzzy Toolbox to ease the process.

The main advantage of using Fuzzy Logic is simplicity and time efficient. Fuzzy Logic uses less processing time compared to other methods (i.e. calculation of loss saving at each bus one by one). Therefore it is possible to make more iteration and obtain more loss reduction with less processing time compared to normal method.

For this method, the load distribution of the system is assumed to be uniform. This fuzzy logic method can be applied to any radial distribution system with any number of buses with only minor adjustments.

As recommendation for future works, the fuzzy logic system can be integrated with neural network to obtain a more efficient result. Neural network can be used to replace the author's logical decision in determining the membership functions by its self-learning ability.
