# FLUORESCENCE INTENSITY POSITIVITY CLASSIFICATION OF HEP-2 CELLS IMAGES USING FUZZY LOGIC 

By<br>Dayang Farzana Bt Abang Sazali

13050

A project dissertation submitted to the Department of Electrical \& Electronic Engineering Universiti Teknologi PETRONAS in Partial Fulfillment of the Requirements for the Degree Bachelor of Engineering (Hons) (Electrical \& Electronic Engineering)

Approved:

Dr. Josefina Barnachea Janier
Project Supervisor

UNIVERSITI TEKNOLOGI PETRONAS
TRONOH, PERAK

## CERTIFICATION OF ORIGINALITY

This to certify that I am responsible for the work submitted in this project, that the original work is my own except as specified in the references and acknowledgements, and that the original work contained herein have not been undertaken or done by unspecified sources or persons.

DAYANG FARZANA BT ABANG SAZALI

#### Abstract

Indirect Immunofluorescence (IIF) is a gold standard used for antinuclear autoantibody (ANA) test using Hep-2 cells to determine specific diseases. Automated interpretation is crucial to assure high accuracy to determine the autoantibody type of diseases. There are different classifier algorithm methods that have been proposed in previous works to classify the fluorescence intensity, however, there is still no valid algorithms to set as a standard. The purpose of this study is to classify the fluorescence intensity by using fuzzy logic algorithm to determine the positivity of the Hep2-cell serum samples. The scope of study of this project involves converting the RGB colour space of images to LAB colour space and the mean value of the lightness channel and chromaticity layer (a) channel is extracted and classified by using fuzzy logic algorithm based on the standard score ranges of ANA fluorescence intensity which are $4+, 3+, 2+, 1+$ and 0 . Based on the results, the accuracy of intermediate and positive class is $85 \%$ and $87 \%$ respectively.

## ACKNOWLEDGEMENT

First and foremost, the author would like to take this opportunity to express her deepest gratitude and thankful to God for His kind blessing by giving a chance, strength and determination to complete her Final Year Project in a good condition, health and well-being. Efforts have been taken in this project, however, it would not have been possible without the kind support and help of many individuals and organizations. The author is highly indebted to Dr. Josefina Barnachea Janier for her guidance and constant supervision as well as for providing necessary information regarding the project and also her support in completing the project.

Special thanks as well to the co-supervisor, Ms. Zazilah Bt. May for her patient guidance in the technical and non-technical knowledge. Not to forget, a special gratitude and thanks to Dr Ibrahima Faye for his support and cooperation in completing the project. The author also would also like to thank Dr. Nazreen Bt Badruddin, the FYP coordinator for conducting several seminars and briefings to assist the FYP students as well as helping to arrange the schedule for ELECTREX and Viva for students by inviting external examiners for evaluation. Besides that, the author thanks and appreciation also goes to her colleagues and beloved families for their endless support and encouragement throughout the duration of the project.

## CHAPTER 1

## INTRODUCTION

### 1.1 Background Study

Autoantibody (AAB) is type of proteins or antibodies that directed against the individual's protein. AAB is produced when the immune systems cannot recognise self and non-self protein. Therefore, the antinuclear antibodies (ANA) test is performed to determine type of autoimmune disease if ANA is positive. There are various developed technologies development to diagnose the disease-specific of AABs such as enzyme-linked immunosorbent assay (ELISA) and multiplexing technologies, however, indirect immunofuorescence (IIF) assay is set as a standard method to perform on human epithelial (Hep-2) cells today.

The immunofuorescence image will be evaluated to determine positive and negative screening results and staining pattern recognition. Previously, the samples classification and pattern recognition is visually evaluated by medical doctor or the experts. As it resulting as time consuming and lack of expertise to diagnose ANA screening, rate of misclassifications errors will be increased. Thus, an automated evaluation is developed in order to decrease the rate of errors [1],[2]. In medical context, computer aided system (CAD) has been successfully employed which serves as second reader capable to examine the image more accurately by reducing errors and works as a training tool for specialized medical personnel.

An ANA Hep-2 test results is considered positive when a clear ANA pattern is observed. There are varieties of patterns for specific disease. According to [3], the study made an analysis on ANA test on healthy individuals and patients with autoimmune rheumatic diseases (ARD). The results obtained from ANA patterns for ARD patient mostly are homogenous, nuclear coarse speckled, and centromeric. Whereas the nuclear fine speckled was observed only in healthy person. In addition, to obtain the specific pattern, dilution of 1:80 is usually used. More description of pattern can be found in [4].

In most research, the classification technique to determine the fluorescence intensity of ANA test still lacks of accuracy. Determining occurrences of auto immune disease is crucial where these AAB are detected by specific fluorescence intensity. Hence, this project intends to presents a system to classify the fluorescence intensity to determine either the serum samples are positive or negative using fuzzy logic algorithm before proceeding with pattern classification.

### 1.2 Problem statement

Some research groups in previous works have proposed different algorithms for the analysis of IIF images. The validation of proposed methods had been carried out on small and private dataset. In this proposal, the author will discuss on the dominant fluorescence intensity of ANA test. The significance on determining the fluorescence intensity of the serum samples is to identify the ANA pattern for a specific autoimmune disease. The proposed method will divide the fluorescence intensity into five classes, which are positive (4+, 3+, $2+$ ), intermediate ( $1+$ ) and negative (0). The crucial issue that needs to be highlighted here are, the datasets are manually interpreted by the medical doctor which resulting in time consuming, no valid standard has been set for the classification due to lack of the accuracy in most research and most of the classification errors are made on the intermediate images since its intensity samples usually exhibit low contrast where even the experts found the classification task difficult.

### 1.3 Objectives

The objectives of this work are:

1. To study and identify different features in images that contributes to positivity and negativity of the samples.
2. To develop classification algorithm using fuzzy logic that is able to accurately divide the images into five classes: positive (4+, 3+, $2+$ ), intermediate ( $1+$ ), and negative ( 0 ).
3. To assess the performance of classification algorithm.
4. To validate the accuracy of classification results.

### 1.4 Scope of Study

Fluorescence intensity of hep-2 cell images are extracts into colour saturation and lightness to determine the classes of the intensity. The image is pre-process and converts the original image to LAB colour space. LAB color space is used to identify different colors in an image by analyzing Luminosity layer (L), Chromaticity layer ' $a$ ' where the color spectrum is from green color to red color (A), and Chromaticity layer ' $b$ ' where the color spectrum is from blue to yellow color (B) [5]. After converting the color space, the mean value of L and ' $a$ ' are chosen as main features for extraction.

Then, fuzzy logic classifier will be used to classify the fluorescence intensity based on the features which are mean value of L , and (a). It uses a fuzzy rule (linguistic IF-THEN statement) and combines with fuzzifying input according to membership function or features to get an output distribution [6].

### 1.5 Relevancy of the Project

This project mainly involves on understanding of image processing and using the knowledge to design algorithm that can be used in medical application. As a whole, this work encompasses digital signal processing knowledge on how each image is represented or interpreted and helps to optimize the exploitation of the information that permits the processing faster.

### 1.6 Feasibility of Project

The time frame to develop the classification algorithm using fuzzy logic depends on how fast the basic designs can be understood. Eight months of time frame to complete Final Year Project (FYP) is feasible for completing the project.

## CHAPTER 2

## LITERATURE REVIEW

### 2.1 Fluorescence Intensity

According to the Centre for Disease Control and Prevention in Atlanta, Georgia, the scores range for fluorescence intensity is divided into two classes which are positive and negative; four subgroups in the positive class are shown in TABLE 1 [7].

Table 1: Fluorescence Intensity Classification Criteria

| Subgroups | Description |
| :---: | :---: |
| $\mathbf{4 +}$ | Maximal fluorescence (Brilliant green) |
| $\mathbf{3 +}$ | Less brilliant green fluorescence |
| $\mathbf{2 +}$ | Defined pattern but diminished fluorescence |
| $\mathbf{1 +}$ | Very subdued fluorescence |
| $\mathbf{0}$ | Negative |

However, the medical doctors in [8] referred to the same guideline (TABLE 1) suggested to classify into three classes, namely positive, intermediate, and negative since the technical problems can affect the test sensitivity and specificity. Hence, the scores range for positive class is $2+$ and above, intermediate class is $1+$ and 0 indicates negative.

### 2.2 CIELAB

Colour space systems are created by Commision Internationale de l'Eclairage or International Commision on Illumination (CIE) in 1931 which defined the CIEXYZ (X-Red, Y-Green, Z- Blue) colour space that represented the entire possible colour by human eyes. As for CIELAB, it contains a large colour gamut that can represent the entire colour visible by the human eyes. Its L component closely matches human perception of lightness. However, as it consists of larger gamut, the
bitmap image represented as LAB requires more data per pixel for computer displays or even human vision. As for RGB colour model, its model has a limited gamut of colour, while CIELAB attempts to model all colours [9]. Besides, according to paper [10] and [11] which evaluates the appearance and colour of food and leukocyte detection for medical image processing, respectively, used $1 * a * b$ colour space as it has uniform distribution of colours, and as well as very close to human perception. Other colour spaces such as RGB and CMYK, in practice, widely used for display and printing, while HSB and HSL are used for colour selection. However, all mentioned colour spaces are subsets of the human colour gamut as measured and defined by CIE which is shows in Figure 1.

Figure 1: CIE Chromacity Diagram

### 2.3 Other Classifier for Fluorescence Intensity

There are automated system with different algorithm implementation have been created. One of it is ALKIDES interpretation systems, it is a helpful tool which is able to analyze different cells and bead-based cells fluorescence assays [12]. It consists of modules for device and autofocus control, image analysis and pattern recognition algorithm. All algorithms of ALKIDES are implemented using C++ programming language and OpenMP for parallelization task. As for autofocus control it is using Haralick's characterization to analyse grey scale transition that
used 6-diamidino-2-phenylindol (DAPI) as fluorescent dye for object recognition and focusing. According to [1], the result obtained using ALKIDES is $90.1 \%$ agreement compared to visual interpretation as for the assessment of data, reactivity index (RI) is calculated by combining the image intensity, contrast, and number of grey-scale levels of the overall image [1].

Other recent approach regarding on the system for fluorescence intensity classifier is by using a Multiple Expert System (MES). There are two types of classifier which work as measurement level: Multi-Layer Perceptrons (MLPs) and Radial Basis Network (RBF). The combination of these classification rules using two neuron outputs that belongs to positive and negative classes and the samples are presented in vector by considering in xy-plane where $(-1,1)$ is negative, $(1,-1)$ is positive and otherwise is dubious (refer to Figure 2) [13]. The point Oi represents the $i$ th output vector. This classification method has an encouraging results and still needs to be improved.

Figure 2: Example of classification rule used to vary the error tolerance of the classification system

The other technology for IIF ANA screening is EUROPattern system. It is a closed system which is fast and comprehensive IIF pattern recognition system providing objective test results. The classification of this software is implemented using k-nearest neighbour ( $\mathrm{k}-\mathrm{NN}$ ) algorithm. As for classification of overall samples, a very high agreement is achieved between both interpretations. The system have achieved a good result as stated in [2] " its sensitivity and specificity amounted to $100 \%$ and $97.5 \%$, respectively, while the positive and negative predictive value were
$99.3 \%$ and $100 \%$ " after a comparison was made with visual interpretation. As mentioned in [12] again, $\mathrm{k}-\mathrm{NN}$ classifier is simpler and performs good classification. It works by memorizing the whole training data and performs classification if the attribute test object matches one of the training examples exactly. Table 2 below summarizes the techniques have been used to classify the fluorescence intensity.

Table 2: Existing Fluorescence Intensity Classifier

### 2.4 Fuzzy Logic

This classifier aims at modeling the human thinking and reasoning and applying the model to problems according to needs. Various types of field have used this classifier in their industry pertaining to requirements.

### 2.4.1 Fuzzy Logic in Health Industry Applications

Events and mechanisms are analyzed in a fuzzy system and can be modeled by considering the related verbal and substantially uncertain information as complementary to the events in preference to equations that are accepted only in implications of certain rules and assumptions [14]. In this paper, new method of fuzzy logic has been proposed besides Sugeno and Mamdani method. The modified Mamdani method is defined by equation (1) and (2) which combining fuzzification formulation of trapezoidal and triangular functions. The 3 methods are performed for cancer risk analysis and the results are compared as shown in the Table 3.

$$
\begin{align*}
& \text { if } a>x \| c<x \Rightarrow 0 \\
& \text { if } a \leq x \leq b \Rightarrow \frac{\max x^{\prime} \times[\sin (x)-\sin (a)]}{[\sin (b)-\sin (a)]} \\
& \text { if } b \leq x \leq c \Rightarrow \frac{\max x^{\prime} \times[\sin (c)-\sin (x)]}{[\sin (c)-\sin (b)]}  \tag{1}\\
& \text { if } a>x| | d<x \Rightarrow 0 \\
& \text { if } a \leq x \leq b \Rightarrow \frac{\max ^{\prime} \times[\sin (x)-\sin (a)]}{[\sin (b)-\sin (a)]} \\
& \text { if } b \leq x \leq c \Rightarrow 1 \\
& \text { if } c \leq x \leq d \Rightarrow \frac{\max ^{\prime} \times[\sin (d)-\sin (x)]}{[\sin (d)-\sin (c)]} \tag{2}
\end{align*}
$$

Table 3: Existing Fuzzy Logic Classifier

| AUTHOR | TECHNIQUE | APPLICATIONS | ADVANTAGES | LIMITATIONS | RESULTS |
| :---: | :---: | :---: | :---: | :---: | :---: |
| A. Yilmaz and K. Ayan <br> (2012) | Modified <br> Mamdani fuzzy logic | Cancer risk analysis | Higher accuracy compared to Sugeno and Mamdani method fuzzy logic. | $100 \%$ accuracy cannot be detected since the risk status of a person having a low risk rate may change in future with different living conditions and factors. | Average Accuracy: |
|  |  |  |  |  | Modified <br> Mamdani :79.5\% |
|  |  |  |  |  | $\begin{gathered} \text { Mamdani } \\ : 76.7 \% \end{gathered}$ |
|  |  |  |  |  | Sugeno: <br> 66.9\% |

Therefore, in this paper, the modified Mamdani method will be used in this study as it results in higher accuracy agreement in analyzing cancer risk.

### 2.4.2 Colour Classification

Fuzzy logic has been used on determining colour based on human perception. In [15], colour classification usually used for colour image segmentation. HSL (hue, saturation, lightness) is used for representing three dimensions. A colour can be coded by giving the membership function with different values of hues range. The other two dimensions ( $\mathrm{S}, \mathrm{L}$ ) are usually divided into three parts: weak, medium and strong. Then, each dimension of S and L will be presented in 1D trapezoidal membership function and then by multiplying those functions, a set of 2D membership function is generated. Further explanation on colour classification can be referred to [15]. FIGURE 3 shown below illustrate a triangular membership function which assumes the value interval $[0,1]$. The membership function is described by the fuzzy set which is colours. Therefore, in this paper, the colour classification can be determined by using fuzzy logic.

Figure 3: Partitioning H dimension with triangular membership function [9]

### 2.4.3 Life Estimation of Phase Angle Controlled Induction Motors

In this application, fuzzy logic is used to estimate the life estimation of an induction motor. There are three feature extractions used that cause the insulation stress: voltage peak, rate of rise of voltage and thermal loss. In addition, the stress input parameters has set to four fuzzy set namely low, medium, high and very high. Then, the triangular membership function is presented with each of features with respect to reference value of fuzzy set [16]. Therefore, from these three features, the estimation life can be estimated by using fuzzy expert system.

Briefly, besides the two applications of fuzzy logic stated above, there are a lot of other application such as image segmentation [17], texture features classification [18] and others. Therefore, in this paper, the aim of this project is to design a fuzzy logic algorithm for the fluorescence intensity of IIF image diagnosis. It is vital as the intensity tends to determine the positivity of the serum sample based on several image's features such as saturation and lightness to determine the autoimmune disease.

## CHAPTER 3

## METHODOLOGY

### 3.1 Research Methodology

This final year project is to be carried out with the following phases (see Figure 4) and the description of each step.

Figure 4: Research Flow

In research stage, general approaches of autoimmune disease detection, identification and classification of AAB Hep-2 cell are studied. Next, the segmentation and pre-processing techniques such as Gaussian filter; median filter, thresholding and etc are studied. The types of colour space for a conversion from RGB are also studied. Besides that, classification techniques such as KNN, MLPs, and RBF are studied. Based on reading and research that have been made, type of colour space, features extraction and classification are chosen.

After finalizing on the techniques, the experimental work is started by executing and initiating the project with MATLAB software prior to implementation. The implementation of the coding will be based on the sequence as shown in the Figure 5 starting from image pre-processing, conversion of colour space, mean calculation and classification. After implementation, the coding is tested and troubleshoots for improvement at the end of the project.

Figure 5: Scheme of Image Processing and Classification
Figure 5 displays the process in order to obtain the mean value of lightness, chromaticity colour $a$, and chromaticity colour $b$, and then classify the features obtained from the training datasets using fuzzy logic. The Hep-2 cell images are acquired from a fluorescence microscope (40-fold magnification) coupled with 50 W mercury lamp with a digital camera (SLIM system by Das slr). The camera has a CCD with square pixel of 6.45 micro-meters. The images have a resolution of 1388x1038 pixels, a colour depth of 24 bits and stored in BMP format. The
biomedical engineer manually segmented the image by using a tablet PC and subsequently, each image was verified and annotated a medical doctor specialized in immunology.

The acquire image is converted to LAB colour space and the mean value of each luminosity layer ' $L$ ', and chromaticity layer ' $a$ ' where colour falls along the red-green axis from the training dataset is calculated and extracted. After obtaining the mean values based on intermediate and positive classes for training purposes (except negative), the rule in the fuzzy logic is given based on the image that contains three input variables of spectrum range as recorded in Results sections.

### 3.2 Flow Chart

Figure 6 displays the flow of approached planned to be carried out in order to realize the idea of the proposed project.

Figure 6: Flow Chart

Figure 7 below shows the flow of process in order to determine the fluorescence intensity classification.

Figure 7: Flow Process of Fluorescence Intensity Classification

### 3.3 Project Tasks

## Research and Study

Research on fuzzy logic methods and applications. study in details on medical context of ANA to diagnose autoimmune disease and image processing. understand all related terms. Journals, thesis, conference papers, and technical reports are referred during this process

## Justifying Choice of Techniques

Based on extended reading on the literature review, LAB colour space and method used for fuzzy logic is selected.

## Learning MATLAB coding

To familiarize with the environment of coding platform with reference of online sources and books.

## Compiling Coding to M File

Once the coding is done, it will be compiled to M-file for running purposes.

## Running Coding

The developed algorithm is run in MATLAB to obtain data for analysis.

## Testing Extraction Coding

To verify and debug the coding of extraction phase.

## Testing Classification Toolbox

To verify and debug the data for classification phase.

## Improvement of Algorithm

Further improvement are done after testing

Figure 8: Project Tasks

### 3.3 Gantt Chart and Milestones

Please refer to the attached document in APPENDIX A.

### 3.4 Tools

This research requires the following software:

MATLAB R2012a :
i. Image Processing Toolbox
ii. Fuzzy Logic Toolbox

## CHAPTER 4

## RESULTS AND DISCUSSIONS

More than 700 datasets were given by MIVIA research lab of the University of Salerno that active in pattern recognition and computer vision. However, the datasets are only consisting of positive and intermediate images. This section will presents and discusses on the findings of this study which classify the classification of fluorescence intensity: $4+, 3+, 2+, 1+$ and 0 . The given images have been segmented and annotated by the experts, hence, the simulations involved are extraction of $L$ and ' $a$ ' mean value and fuzzy logic classifications.

### 4.1 Feature Extractions

Table 4 shows three extraction values after converting the original image into LAB colour space of two types fluorescence intensity; positive and intermediate. The mean value of each layer of the converted image which is lightness, chromaticity (a) and chromaticity (b) are calculated and extracted as shown. The value of positive and intermediate intensity shows a distinct difference. 721 train databases have evaluated and the mean value of lightness, chromaticity (a) and (b) are shown in the APPENDIX B. After obtaining all mean values of the train datasets, the graph of positive and intermediate intensity is plotted in APPENDIX C and APPENDIX D from the lowest to highest of each mean values. Both graph shows that there is a few datasets that are overlapping and shows in a distinct ranges.

Table 4: LAB Features Extractions

| No. | Original Image | Lightness (L) <br> Image | Chromaticity (a) <br> Image | Chromaticity (b) <br> Image | Fluorescence Intensity |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | P |  |  |  |  |

Table 5: Ranges of LAB Mean Value for Positive, Intermediate and Negative Class

| CHANNEL | POSITIVE | RANGES (MEAN) |  |
| :---: | :---: | :---: | :---: |
|  | INTERMEDIATE | NEGATIVE |  |
| $\mathbf{L}$ | 5.987 to 54.782 | 3.13 to 14.8 | $<3.13$ |
| $\mathbf{A}$ | -9.178 to $(-53.286)$ | -4.439 to $(-22.294)$ | $<-22.294$ |
| $\mathbf{B}$ | 8.386 to 55.078 | 4.225 to 20.434 | $<4.225$ |

After obtaining the mean values based on intermediate and positive classes for training purposes, channel L and channel ' $a$ ' are selected as both of it satisfied and highlighted the criteria of fluorescence intensity. Meanwhile, negative class value is chosen lower than the intermediate minimum value as the class of negative is not provided in the datasets. The rule in the fuzzy logic is given based on the image that contains two input variables (Channel L and Channel A) as recorded in spectrum range as shown in Table 5.

### 4.2 Fuzzy Logic Classification

Figure 9 below shows the fluorescence intensity fuzzy logic model with two parameters; mean value $L$ and mean value $a$ are taken as inputs and one output with 5 membership functions which are classes of fluorescence intensity: $4,3,2,1$ and 0 .

Figure 9: Fluorescence Intensity Fuzzy Logic Model

Based on the range recorded from the experimental results, the Lightness input parameter is classified as dull and bright according to the magnitudes while ' $a$ '
is classified as very bright green, bright green, medium green, low green and red. The membership functions for lightness and chromaticity colour $a$ are shown in Figure 10 and Figure 11 shows the trapezoidal and triangular membership functions are selected for the input as well as the output.

Figure 10: Membership Function for ' $L$ ' Mean Value

Figure 11: Membership Function for ' $a$ ' Mean Value

The membership functions and the rules are framed by considering all the possible combinations of the inputs computed from the experimental results. A total of 6 rules are framed (see Figure 12). The test data is computed in per unit value from 0 to 1 . The output of the fuzzy expert systems is presented in Table 6 .

1. If ( $A$ is Red) and ( $L$ is Dull) then (Fluorescence_Intensity is 0 ) (1)
2. If ( A is Red) and ( L is Bright) then (Fluorescence_Intensity is 0 ) (1)
3. If ( $A$ is LowGreen) and ( L is Dull) then (Fluorescence_Intensity is +1) (1)
4. If ( $A$ is MediumGreen) and ( $L$ is Bright) then (Fluorescence_Intensity is +2 ) (1)
5. If ( A is BrightGreen) and ( L is Bright) then (Fluorescence_Intensity is +3 ) (1)
6. If ( A is VeryBRightGreen) and ( L is Bright) then (Fluorescence_Intensity is +4 ) (1)

Figure 12: Fuzzy Rule

Table 6: Class of Fluorescence Intensity Based on Fuzzy Logic Output

| Class | Output |
| :---: | :---: |
| 0 | $0.00-0.20$ |
| +1 | $0.21-0.40$ |
| +2 | $0.41-0.60$ |
| +3 | $0.61-0.80$ |
| +4 | $0.81-1.00$ |

Figure 12 shows the 'if-then' linguistic statement or rules based on the inputoutput membership functions. There are 6 rules shown. The results will show 0 (negative) when there is red colour existing regarding any lightness. Four classes of positive intensity is decided according to range of input variables.

After all the rules in the fuzzy logic are framed, 200 datasets are tested. The output variables are classified into 5 classes which are $0,1,2,3$ and 4 . Negative and intermediate class is indicated by 0 and 1 respectively, while from 2 to 4 is positive that divided to 3 classes corresponds to its intensity as shown in Figure 13.

Figure 13: Fluorescence Intensity Output

The graphical application of the fuzzy rules shows a positive Hep-2 cell image when $L$ mean value is 29.3 and ' $a$ ' mean value is -33.4. as shown in Figure 14. The features of input parameters corresponding to L and ' $a$ ' mean values are shown at the top of the respective blocks. The defuzzification of the resultant membership function is performed using largest output maximum (lom) algorithm that shows on the last block of the resultant output - Results.

Figure 14: Graphical Application of Fuzzy Rules for Positive Results
The observation can be made based on the figure for positive class is, the output membership function consists of five triangles start from $0,1,2,3$, and 4 , and the shaded blue colour is mostly on the third triangle and results in class of 2-positive with an output of 0.73 .

Figure 15: Graphical Application of Fuzzy Rules for Intermediate Results

Fuzzy Logic Classification

## Results

0.74

Image is Positive 3

Figure 16: Graphical User Interface (GUI)

On the other hand, the intermediate class (Figure 15) is on the second triangle function indicates intermediate class with an output of 0.31 . Figure 16 shows the GUI that has been created for the ease of use and as the primary interface for humanmachine interaction.

Referring to APPENDIX E and APPENDIX F, 200 datasets of positive and intermediate fluorescence intensity are used for testing the performance measurements of fuzzy logic. It is seen that, 15 out of 100 intermediate data and 13 out of 100 positive data held in fuzzy logic classifier are misclassified, then, the accurate results are obtained and performance measurement is ensured at a rate of $85 \%$ for intermediate class and $87 \%$ for positive class. However, larger database is needed to observe the accuracy of the proposed method.

## CHAPTER 5

## CONCLUSION AND RECOMMENDATION

In conclusion, this project aims to classify the fluorescence intensity of Hep-2 cells fluorescence image to determine specific diseases through ANA test. In most research, there is still no validation of proposed methods from other research groups. Therefore, fuzzy logic classifier is proposed in this study.

Based on research that has been done, LAB colour space is selected as the entire colour is visible and close to human perception. It consists of three features that can be measured which are lightness, chromaticity (a) and chromaticity (b). After the RGB or original image is converted to LAB colour space, the mean value for two main features: L and ' $a$ ', are calculated and the range is obtained from the experimental on training datasets. The ranges for two features then are used in the input variable for fuzzy logic classifier. Type of fuzzy logic used in this study is the modified Mamdani method as it uses triangle and trapezoid membership functions. As the output result of data received from these factors, the classes of fluorescence intensity can be determined.

From the results that have been obtained, it is seen that the proposed algorithm provides full information for the classifications and shows that the fuzzy expert systems is reliable with high agreement of accuracy measurement which are $85 \%$ for intermediate class and $88 \%$ positive. However, $100 \%$ accuracy in the system could not be detected as there are few datasets determine by the expert (medical doctor) may be misclassified and needs to be further analyzed.

As the results are encouraging, in the future, a large database will be engaged to further test and improve the developed tools.
