## **ABSTRACT**

This project is about Human Epithelial type 2 (HEp-2) Cell Images Feature Extraction Based on Textural and Statistical Analysis. The medical industries have yet to found any reliable solution in differentiating the Anti-Nuclear Antibodies disease according to its cell pattern. Current practice, subject to physician's expertise, is not very reliable and cannot be reproduced. The main objective of this project is to provide significant differentiable features based on textural and statistical features of the HEp-2 cell images. The textural features are basically based on the surface of the cells which are analyzed from the grayscale images of the cells. The features are later classified to test its reliability. In this project the images will be analyzed in grayscale mode and processes using two different order of statistical analysis. The second order statistical analysis contains the textural features representation. It was found out that homogeneity and correlation of patterns are the same. Hence, avoid using this feature in order not to have wrong classification information. Also not all Gray-Level Co-occurrence Matrices (GLCM) properties features can be used to differentiate HEp-2 cell patterns. At the end of this project, the results shows that the use of textural (second order statistical) analysis is beneficial to get better accuracy of classification, though it still depends on the type of classifier used.

## **ACKNOWLEDGEMENT**

First and foremost, the author would like to take this opportunity to praise the Almighty God for giving an utmost opportunity for the author to accomplish this final year project as part of the requirement for Bachelors of Engineering (Hons.) in Electrical & Electronics Engineering at Universiti Teknologi PETRONAS.

Secondly, the author is grateful for all the supports shown by parents. They have continuously provided moral and financial supports until the end of this project. Also a big ‘thank you’ to the assigned supervisor for this project, A.P Dr. Josefina Barnachea Janier who has sacrificed her time in giving guidance, moral support, and necessary improvements from start till the end of the project.

Special thanks to the co-supervisor, Ms. Zazilah Bt. May, for her precious guidance and help in providing information towards completing this final year project. The author would also like to thank Dr. Nasreen Bt. Badruddin, the FYP coordinator for conducting briefings and seminars in order to provide useful information in the completion of the final year project.

Last but not least, the author would like to express her gratitude to fellow colleagues who have always provided moral supports and never-ending assistance in ensuring this final year project is finished within the given time frame.

# **CHAPTER 1**

## **INTRODUCTION**

### **1.1. Background of Study**

Human Epithelial type 2 (HEp-2) cells are the additional substance that have been used in order to act as the binder for the anti-nuclear antibody (ANA) in which the ANA will bind to the nucleus of the HEp-2 cell [1]. HEp-2 cells are used in analyzing ANA disease as it can detect a large range of antigens and has a high sensitivity towards the presence of the antigens [2]. Indirect Immunofluorescence (IIF) with HEp-2 cells has been used to detect antinuclear auto-antibodies for diagnosing systemic auto-immune diseases. The IIF will appear in different fluorescence patterns to determine different types of auto-immune diseases.

Based on current practices, these patterns are differentiated manually by specialists and basically took a long time to obtain the result [3]. In addition, the result might vary since it depends on the experience of the specialist which can affect the reliability of the result and the reading cannot be reproduced officially for future reference [4]. Therefore, in order to ensure that the result for pattern classification of this HEp-2 cells is reliable and standardized according to its patterns' features, there have been studies on developing a Computer-Aided Diagnosis (CAD) systems that can automatically classify the pattern according to a standard algorithm [4].

To complete the classification process, it must be aided with supporting information regarding the pattern itself. These can be done by extracting the features of each pattern and the data can be used for classification. According to [5], there are five(5) features that can be extracted from an image. The features are; averaging, edges, simple neighborhoods, motion, and texture. Each feature has different method to extract and to use in different applications.

Basically the process covers three main parts that is pre-processing of the originally captured images, region of interest analysis, and finally the features extraction based on textural and statistical evaluation. Four (4) main patterns that are significant to HEp-2 cells are (a)homogeneous, (b)speckled, (c)nucleolar, and (d)centromere accordingly as shown in Figure1.

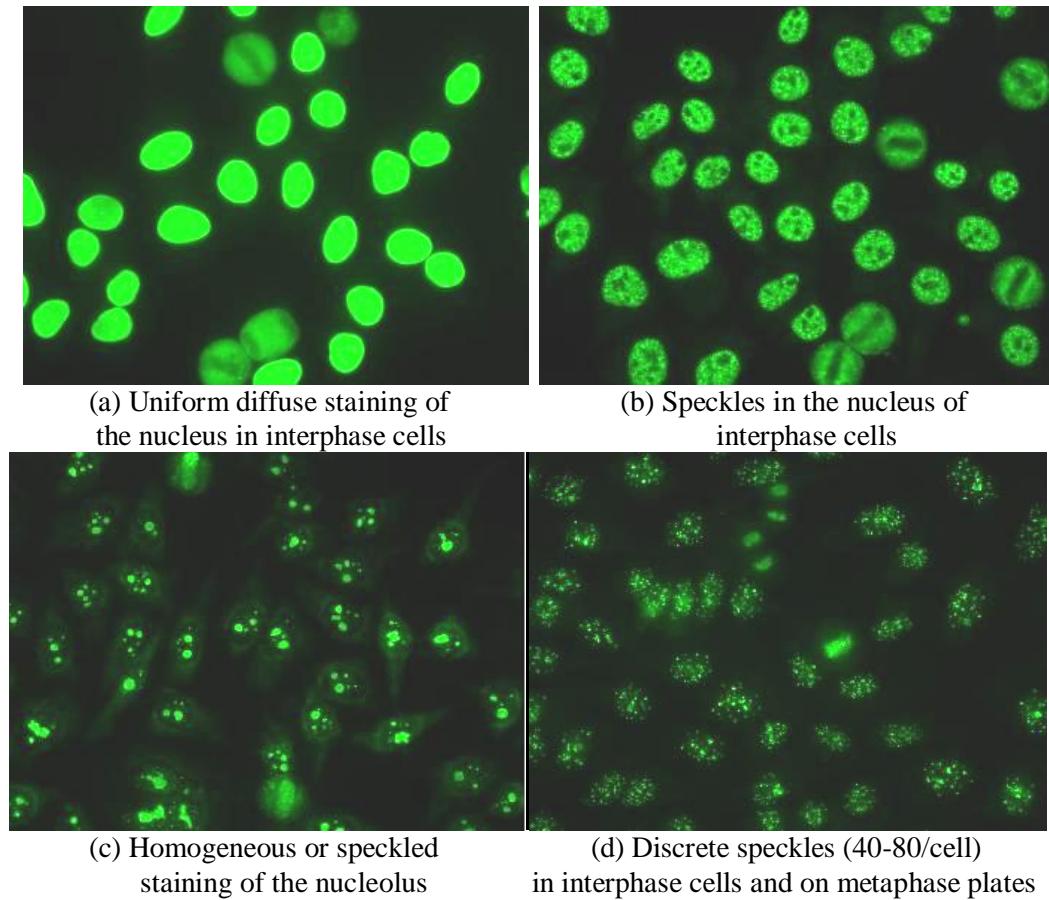

Figure 1: Four Different Types of HEp-2 Cell Images (a) Homogeneous (b) Speckled (c) Nucleolar (d) Centromere [6]

## 1.2. Problem Statement

Current techniques of pattern classification available in literature have some limitations in terms of performance and accuracy in determining the main patterns namely homogeneous, speckles (fine and coarse), centromere, and nucleolar. Correct identification of features is necessary in producing accurate information that is essential in developing automated classification system that can identify patterns accurately and reduce the time required for diagnosis.

### **1.3. Significance of the Project**

- To improve the current practice used in the medical institution, by developing standard method for classification purposes
- To apply the best image processing techniques for feature extraction and statistical representative of cell patterns

### **1.4. Objectives**

This project will be focusing on extracting the image textural and statistical features for five (5) major patterns; homogeneous, fine-speckled, coarse-speckled, nucleolar, and centromere. Below are the objectives of this project:

- To identify textural and statistical features to be utilized to differentiate each pattern
- To measure the texture difference between the patterns
- To assess the reliability of each textural representation by distinguishing one from the other
- To test the accuracy of classification using the extracted features

### **1.5. Scope of Study**

Overall, this project covers five main types of HEp-2 cell patterns which are; homogeneous, fine-speckled, coarse-speckled, nucleolar, and centromere.

### **1.6. Feasibility of the Project**

From the literature done, it was found that some parts of the project were already done by some researchers on other types of images. Some of the researches are focusing on HEp-2 cell images but among those researches none of it summarized the texture of the cells for each pattern types. Therefore using current available application, Matlab, the project will utilize its image processing tools to implement the functions in aiding the medical industries with specific data range representing the textural and statistical information of each pattern. Finally, after summarizing the processes to be done, this

project is possible to be completed within the time range specified for Final Year Project I (FYP I) and Final Year Project II (FYP II).

## CHAPTER 2

### LITERATURE REVIEW

#### 2.1. Critical Analysis

##### 2.1.1. Textural Feature Extraction

Recently, there has been a lot of studies on the classification of HEp-2 cell images in conjunction towards developing a reliable and standardize system to analyze and classify different types of ANA. According to Ghosh & Chaudhary [4], four types of feature extraction have been done towards the same data set in order to compare the successfullness. The first feature is by using Speeded-up Robust Features (SURF) that function by detecting the key-points of an image and store it in a vocabulary for further classification. SURF technique is used for static signature (image of the signature) verification with range of equal error rate (EER) between 14.5% - 19% [7].

The second feature extraction technique is based on Region of Interest (ROI) that focuses on the cell nuclei or clusters of cell nuclei which later can be classified according to its sub-feature [8]. For HEp-2 cell images, the sub-features used include the standard deviation of the gray values, the 30th ( $P_{30}$ ) and 60th ( $P_{60}$ ) percentiles of the gray values in the ROI, the percentile range ( $P_{range} = P_{60} - P_{30}$ ), and the roundness of the ROI [4]. For the third feature, textural, the cell images will be evaluated in its gray-scale. Disregard its original colors, by using Grey-Level Co-occurrence Matrix (GLCM) where the intensity of the gray level will be taken into account. The main criteria involves in this extraction type is the texture and tone of the image which is closely related together and its presence are inversely proportionate between each other [9].

Lastly is the Normalized Histogram of Oriented Gradient (NHOG) feature. This feature extracting method has been used in pedestrian detection by camera sensor in intelligent vehicle where the statistic of the gradient map of target image will be extracted in histogram manners [10]. Referring to Ghosh & Chaudhary [4], who had

done the feature extraction using all four (4) features, the successful rate is listed in Table 1. Moreover, Tsu-Yi *et. al* [11] in their paper discovered the average accuracy of using textural feature analysis to differentiate the patterns is 80.3%. Therefore for this paper, the textural features of the HEp-2 cell images will be used in the feature extraction stage.

Table 1: Intensity-wise, class-wise, and overall accuracy (in percentage) for each feature [4]

Feature Type	Percentage of Accuracy								Overall	
	Intensity-wise		Class-wise							
	Positive	Inter	HO	FS	CS	NU	CY	CE		
<b>HOG</b>	83.84	80.31	82.67	64.89	93.58	70.59	82.76	89.42	82.25	
<b>Texture</b>	90.40	81.54	87.33	68.09	96.33	86.27	68.97	93.75	86.39	
<b>ROI</b>	80.56	50.78	87.33	0	88.99	58.82	86.21	70.19	67.13	
<b>SURF</b>	77.53	57.85	68.67	44.68	59.63	76.47	84.48	75.96	68.67	

### 2.1.2. Statistical Feature Extraction

The statistical features of an image is important in automatic image processing by computers as it is the only way that the computer could recognize and identify the image features. It differs with human that can recognize an image from natural and geometric language [12]. Computer can only recognize information that is transferred using its language.

Therefore, prior to classifying HEp-2 cell images, the statistical features must be extracted to obtain the required data. These data is calculated based on statistical formulas such as; mean standard deviation, and variance [13]. The formula is calculated from the gray intensity level obtained from the gray-scale images. Athilakshmi *et. al* in [13] used the statistical feature to identify the quality of lumber and use the correlation coefficient to justify the pass level for the lumber quality. Lumber is wood material that has been manufactured into boards. The quality level of lumber is important to produce good quality furniture and structures.

In 2010, Vasconcelos *et. al* [14] used statistical method to represent the textural features of lung to identify if the lung is emphysema or not. To represent these features, several descriptors are used. Table 2 shows the list of statistical measures and its corresponding textural measures used in [14].

Table 2: Statistical Measures and Corresponding Textural Representation

Statistical Measures	Textural Measures
<b>Angular Second Moment (ASM)</b>	Degree of uniformity, energy
<b>Entropy (ENT)</b>	Randomness
<b>Inverse Difference Moment (IDM)</b>	Local homogeneity
<b>Correlation (COR)</b>	Linear dependency of gray levels
<b>Contrast (CON)</b>	Intensity variation between a pixel and its neighbor, over the region

## 2.2. Framework of the Study

Based on the literature review and critical analysis done, none of the researches have specified which of the textural representation is valid, in terms of statistical representation, to be used as the indicator of the pattern characteristic. Therefore, this project will focus on extracting the textural features together with the use of statistical representation. Eventually, this project will highlight the reliable textural measures that can be used in identifying the patterns. These measures must have significant difference between each pattern before it can be finalized as the best data to be extracted for classification purposes.

## **CHAPTER 3**

### **METHODOLOGY**

#### **3.1.Image Acquisition**

All images used in this project are acquired from MIVIA Data Set for 21th International Conference for Pattern Recognition. The images were taken by a fluorescence microscope (40-fold magnification) coupled with a 50Wmercury vapor lamp and with a digital camera (SLIM system by Das srl). The original size of the images is 1388x1038 pixels, with 24bits color depth [15].

#### **3.2.Techiques Involved**

##### **3.2.1. Pre-Processing**

Every image processing must start with a pre-processing stage to obtain a clearer image and to suppress the background noise. For this project, the pre-processing will include transforming the original cell images into grayscale image. Other steps may include photometric or colorimetric processes, noise suppression, adaptive filters, and image re-sampling [12].

Basic image processing will be implemented such as segmentation and noise filtering to enhance the image quality before extracting the features.

##### **3.2.2. Feature Extraction**

Since this project will be using textural based feature extraction, all the texture information will be analyzed using particular statistical measures to extract the image features. The statistical measures will then be gathered to analyze the textural features represented. From Figure 1, it is significant that the four patterns have different uniformity level. Therefore, the angular second moment in statistical method can measure the closeness of the element distribution which represents the homogeneity characteristics.

Other textural features can be calculated using other statistical representation that will be explored further in order to find suitable measures that can distinguish the

difference between each pattern. The GLCM is basically a method that transforms the image layout into intensity grid where each of gray level intensity will be represented by numbers according to its intensity level. The numbers will later be calculated according to the specific formula to describe the texture.

### **3.2.3. Data Acquisition**

From the extracted information of the textural features, the data will be compiled together and analyzed accordingly. The data will be used to compare the patterns' difference. The texture of the patterns can be analyzed from the range of values extracted. All data obtained was cross validated between each textural representation and to conclude which of the representation is reliable to be used in extracting HEp-2 cell images in order to provide pre-information for classification process.

### **3.2.4. Pattern Classification**

The acquired data is used as a training input to the classifier to check the features' reliability to differentiate the pattern accordingly. This project is using three (3) and five (5) points  $k$ -NN and ADABoostM2 as the classifier.

### 3.3.Flow Chart

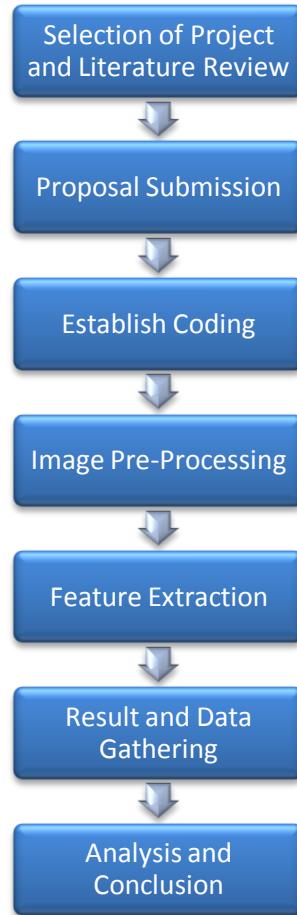

Figure 2: Project Flow Chart

### 3.4.Project Activities

The author attended a short course on image pre-processing technique and learnt the standard pre-processing procedures and how to simulate it using MATLAB application. Below is part of the available commands in MATLAB image processing toolbox that can be used directly by calling the function:

#### 1. Read image

```
% Declare a figure to display images
figure(1);
% Read and image named Koala with JPEG extension and put it in
% a variable
% named 'Image'
Image = imread('Koala.jpeg');
```

## 2. Show image

```
% display the image and give it a title  
imshow(Image), title('Original image');
```

## 3. Convert original image to gray-scale

```
% convert the image to grayscale and put it in a variable  
named 'ImageGray'  
ImageGray = rgb2gray(Image);
```

## 4. Convert gray-scale image to negative image

```
% Compute Image negative  
NegativeImage = 255-ImageGray;  
% display negative image in the third quadrant
```

## 5. Compute log image

```
% Compute log image  
LogImage = log(1+double(ImageGray));
```

Weekly meeting with supervisor and co-supervisor are held to update the progress of the project and to discuss if there are any changes needed.

## 3.5. Tools and Equipments Required

This project mainly used three applications as listed in Table 3.

Table 3: Applications Required for the Project

Application	Version	Description
<b>MATLAB R2013a - Image Processing Toolbox</b>	8.1	To use the image processing toolbox in processing the images and retrieving the data
<b>Microsoft Office Excel 2010</b>	14.0	For data gathering and analysis
<b>Microsoft Office Word 2010</b>	14.0	Documentation purpose

## CHAPTER 4

### RESULTS AND DISCUSSIONS

#### 4.1.Pre-Processing

For texture feature extraction, most of the papers noted that it is best not to over-preprocessing the image to avoid texture changes. Therefore, before extracting the image features, the image are only converted into grayscale using below coding. 40 images of each pattern are used throughout this project which total up equals to 200 images as five patterns are used as reference. The patterns are; homogeneous, fine-speckled, coarse-speckled, nucleolar, and centromere.

```
% Read Image  
Image = imread('E:\Documente\FYP\ANA_Images\All\Speckled\Test3\1.tif');  
% Converting RGB image into Grayscale  
Image2 = rgb2gray (Image);
```

##### 4.1.1. Statistical Analysis

The statistical features of the images are extracted based on first order statistics derived from the histogram of the grayscale image. The features extracted are listed in Table 4 together with its formula, as stated in [16]. These first order statistical measures are based on the intensity of every single pixels of an image without considering the relationship with neighboring pixels. The first order statistical measures observe the distribution of color intensity of the images.

##### 4.1.2. Textural Analysis

Texture analysis of an image is basically extracting the image color intensity using second order statistical measures. To differentiate from the first order statistic, second order statistical measures consider the relationship between each pixel to its neighboring pixels.

Table 4: First Order Statistics [16]

Parameters	Description	Formula
<b>Mean, <math>\mu</math></b>	Average value of the distribution.	$\mu = \sum xP(x)$ $x = \text{gray intensity value}$ $P(x) = \text{probability of } x$
<b>Variance, <math>\sigma^2</math></b>	A measure of how far the gray intensity spread out for the image.	$\sigma^2 = E[(x - \mu)^2]$ $E = \text{expected value of } (x - \mu)^2$
<b>Skewness, <math>s</math></b>	A measure of the extent to which the gray intensity distribution "leans" to one side of the mean.	$s = \frac{E(x - \mu)^3}{\sigma^3}$ $\sigma = \text{standard deviation of } x$
<b>Kurtosis, <math>k</math></b>	The measure of "peakedness" of the histogram.	$k = \frac{E(x - \mu)^4}{\sigma^4}$
<b>Entropy, <math>S</math></b>	The probability of the same intensity to occurs throughout the image.	$S = -k_B \sum_i p_i \ln p_i$ $k_B = \text{Boltzmann's constant}$

## 4.2. Feature Extraction

Using the grayscale image, an array of GLCMs is generated using multi-direction to get the average values from all directions.

```
% Create the GLCMs. Call the graycomatrix function specifying the
% offsets
% Angle set to 0, 45, 90, 135 degree
glcms = graycomatrix(Image2,'Offset',[0 1; -1 1; -1 0;-1 -1]);
```

The offset values are defined according to which angle of the correlations to be taken based on the list in Table 5, where D is the distance between the center of a pixel and the center of its neighboring pixel. For example in Figure 3, it shows the angle of the reading with distance, D = 1.

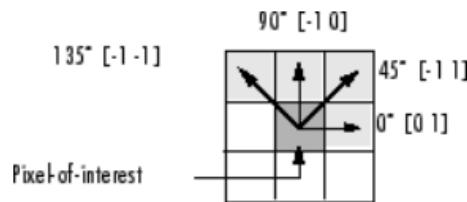

Figure 3: Offset Values with distance, D = 1

Table 5: Offset Values in GLCM[16]

Angle (°)	Offset
0	[0 D]
45	[-D D]
90	[-D 0]
135	[-D -D]

Using 'graycoprops' functions in Matlab, the properties of the gray-level co-occurrence matrices are extracted, which resulting a few sets of arrays based on the number of offset used. The properties are as in Table 6.

The result appears in sets of arrays,  $(i,j,n)$ , where  $i$  and  $j$  represents the row and column numbers, and  $n$  represents the offset number. For example,  $A(:, :, 1)$  is an array of rows and columns for offset [0 1],  $A(:, :, 2)$  for offset [-1 1] and so on.

```
% Derive statistics from the GLCMs using the graycoprops function.
stats = graycoprops(glcms,'Contrast', 'Correlation');
stats2 = graycoprops (glcms, 'Homogeneity', 'Energy');

% Display the statistical values derived from GLCM
display(stats);
display(stats2);
```

Table 6: Gray-Level Co-occurrence Matrix Properties - Graycoprops [16]

Property	Description	Formula
<b>Contrast</b>	A measure of the intensity contrast between a pixel and its neighbor over the whole image. Contrast = 0 for constant image	$\sum_{i,j}  i - j ^2 p(i,j)$ $p(i,j) = \text{probability of } (i,j) \text{ coordinate in GLCM}$
<b>Correlation</b>	A measure of how correlated a pixel is to its neighbor over the whole image. Correlation = -1 or 1 for a perfectly positively or negatively correlated image	$\sum_{i,j} \frac{(i - \mu_i)(j - \mu_j)p(i,j)}{\sigma_i \sigma_j}$ $\mu = \text{mean}$ $\sigma = \text{standard deviation}$
<b>Energy</b>	Sum of squared elements in the GLCM. Energy = 1 for constant image	$\sum_{i,j} p(i,j)^2$
<b>Homogeneity</b>	Measures the closeness of the distribution of elements in the GLCM to the GLCM diagonal. Homogeneity = 1 for a diagonal GLCM	$\sum_{i,j} \frac{p(i,j)}{1 +  i - j }$

Applying all of the properties over the grayscale image, a set of values will be obtained for the analysis. These values will be used for further analysis using statistical measures such as mean, variance, and entropy.

### **4.3.Discussions**

Initially, the images analyzed are mixed between positive and intermediate positivity level. The result shows unbalance reading between both positivity levels. Therefore, the images are later separated, and only positive level images are being used for this project. All data can be found in Appendices. The graphs shows the features level representing all five patterns as; H-homogeneous, F-fine-speckled, S-coarse-speckled, N-nucleolar, C-centromere. The data extracted from the images are plotted into graph to visualize the difference between the patterns. The *x*-axis represents the image name according to its number, while the *y*-axis represents the value of corresponding graph data.

#### **4.3.1. First Order Statistics**

The mean distribution in Figure 4 shows that all of the patterns have almost the same average gray intensity. Except some of the images have a bit higher mean values. This shows that all of the patterns have an average gray intensity level. While centromere's intensity level variance are higher than other patterns' as shown in Figure 5, indicating centromere has more varieties of gray level distribution compare to other patterns.

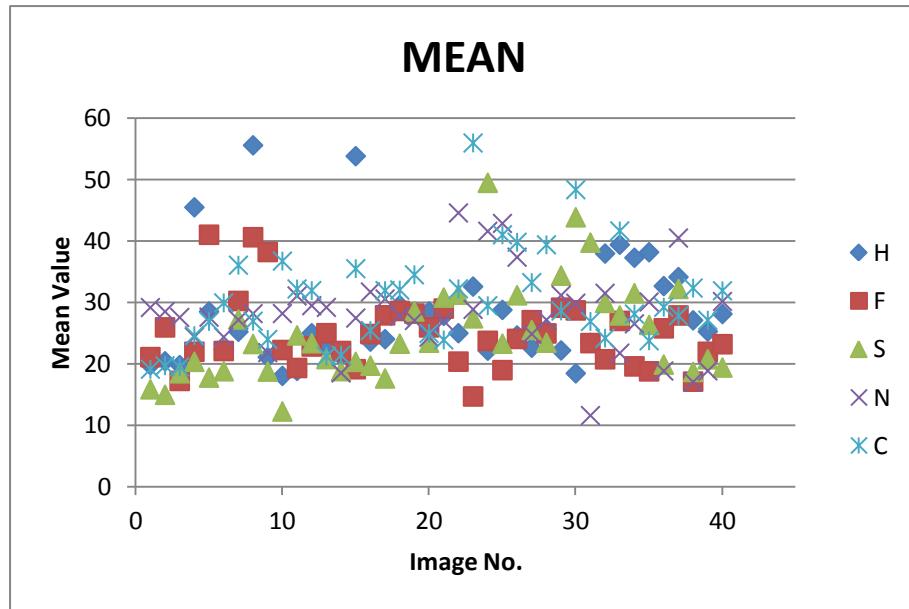

Figure 4: Comparison Chart - 1st Order Statistics (Mean)

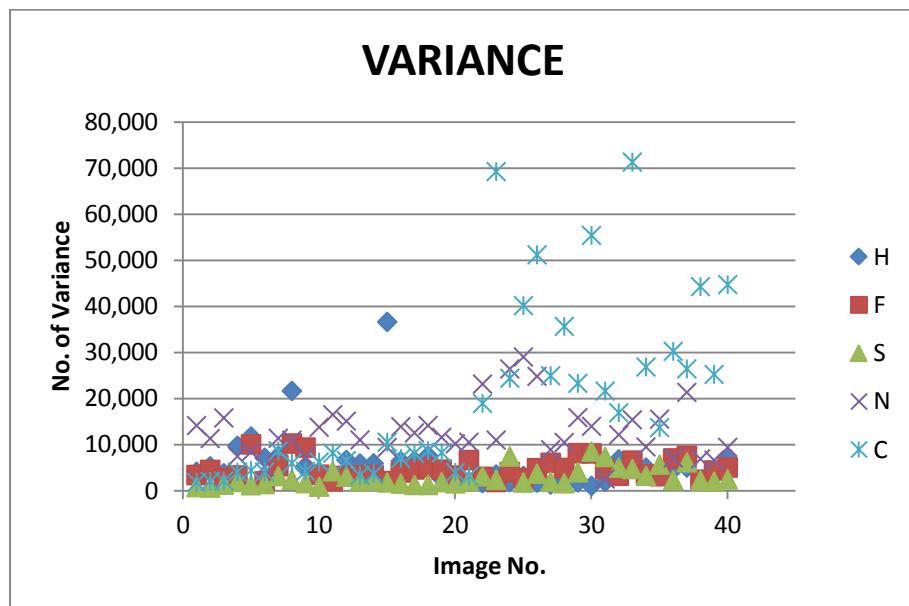

Figure 5: Comparison Chart - 1st Order Statistics (Variance)

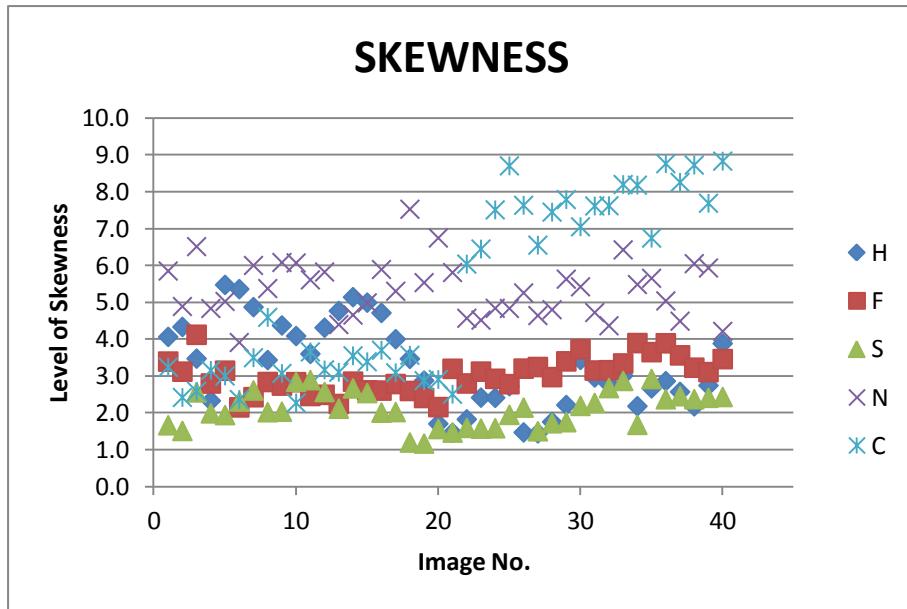

Figure 6: Comparison Chart - 1st Order Statistics (Skewness)

On the other hand, the skewness and kurtosis of the histogram shows the same distribution pattern where nucleolar and centromere have slightly high skewness and kurtosis level than homogeneous, fine-speckled and coarse-speckled. These are shown in Figure 6 and Figure 7. This concludes that the gray level intensity distribution of nucleolar and centromere is highly uneven between the right side and the left side of the mean. The high kurtosis value of nucleolar and centromere represents the narrow peak of the histogram. In other words, nucleolar and centromere pattern has minimum intensity level with high probability distribution.

Meanwhile, for entropy features in Figure 8, homogeneous shows an uneven distribution of entropy level. In average, coarse-speckled have higher entropy than other patterns. High value of entropy indicates highly distributed gray level intensities throughout the image.

For example, in Table 7, the mean of each pattern is the same as each pattern have an average size of images. Larger image might give larger mean values. The variance of gray level for nucleolar and centromere is relatively high compared to homogeneous, fine-speckled, and coarse-speckled. This means that nucleolar and centromere has significantly more gray levels than other patterns.

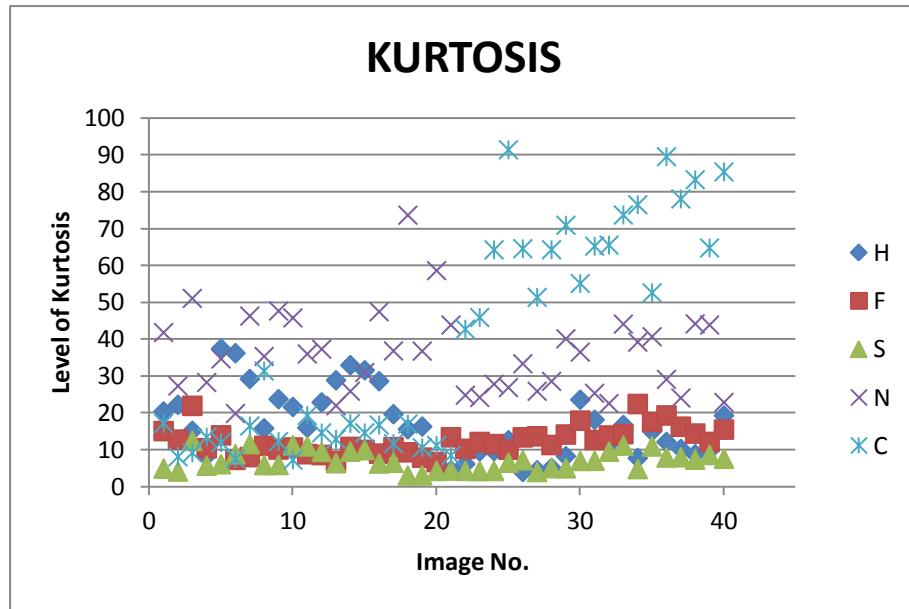

Figure 7: Comparison Chart - 1st Order Statistics (Kurtosis)

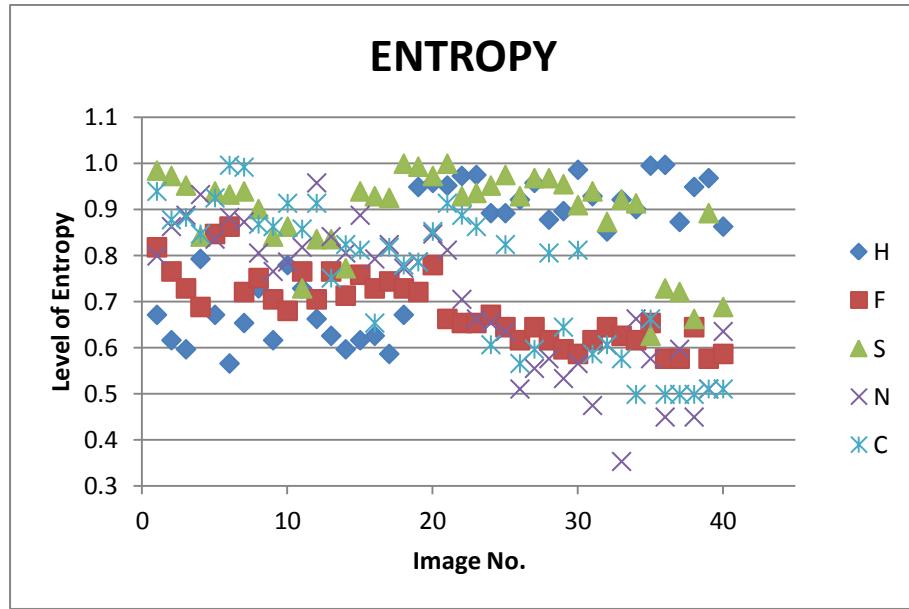

Figure 8: Comparison Chart - 1st Order Statistics (Entropy)

The average skewness of the histogram shows that all patterns have the right side of mean distribution tendency. While the kurtosis values which represent the flatness of the histogram, shows that coarse-speckled has the most flat histogram peak. This indicates the average distribution of gray level in the image as the distribution around the peak is fairly spread across the histogram as in Figure 9. To be compared with centromere's high

value of kurtosis that indicates the sharp peak of the histogram with a wide tail in Figure 10.

The entropy features, representing the measure of the "disorder" of a system, show that the patterns are averagely disorder with values all above 0.5.

Table 7: Average 1st Order Statistics for Each Pattern

Pattern	Mean	Variance	Skewness	Kurtosis	Entropy
Homogeneous	28.1424	5606.3436	3.2622	16.6583	0.8066
Fine-Speckled	24.7734	4607.4190	3.0173	12.4124	0.6854
Coarse-Speckled	24.8844	2757.1519	2.1062	7.0295	0.8891
Nucleolar	28.1622	12531.9148	5.3465	35.8125	0.7066
Centromere	30.4958	19403.8231	5.2912	39.3747	0.7524

#### 4.3.2. Second Order Statistics

For second order statistics, four main functions in Matlab stated in Table 6 are utilized to analyze the texture of the images. Those calculations are done based on GLCM version of the image.

The image processing on contrast returns a comparable value that distinguishes coarse-speckled features from other pattern since it has higher contrast value. While the other four pattern have a little bit overlapping between each other. This is shown in Figure 11. The contrast basically gives the measurable value of the total gray level contrast of the image.

The correlation level of each patterns are significantly constant between each other and not very reliable to be used as differentiator. The overlapping is laid out in Figure 12. The correlation measures how the pixel related to neighboring pixels and calculates the repetition.

Figure 13 shows that coarse-speckled pattern have less homogeneity than other patterns. It computes the clustering of the surface texture, if it is evenly spread or roughly spread on the pattern. While the energy of nucleolar and centromere able to differentiate those two patterns from others even though without using auto-computed system as plotted in Figure 14.

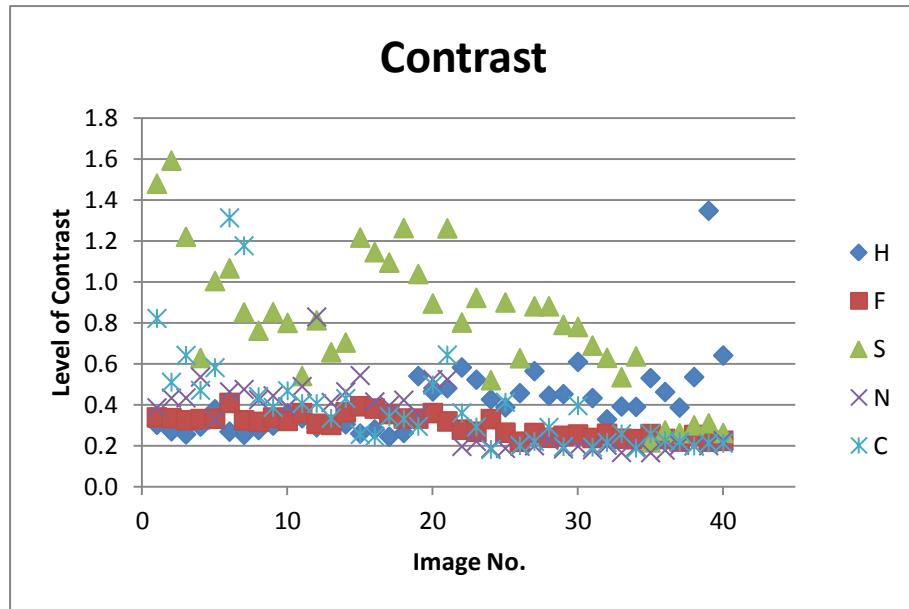

Figure 11: Comparison Chart - 2nd Order Statistics (Contrast)

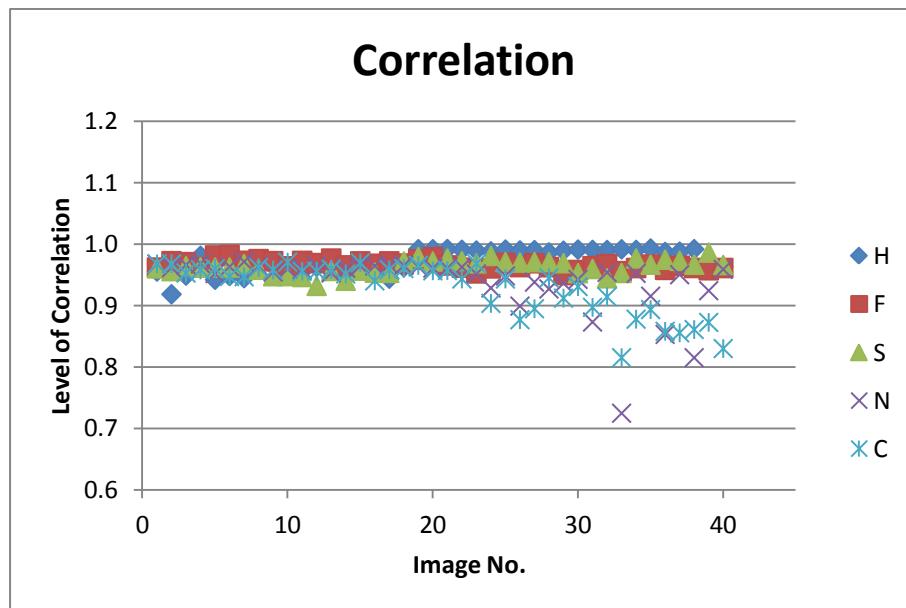

Figure 12: Comparison Chart - 2nd Order Statistics (Correlation)

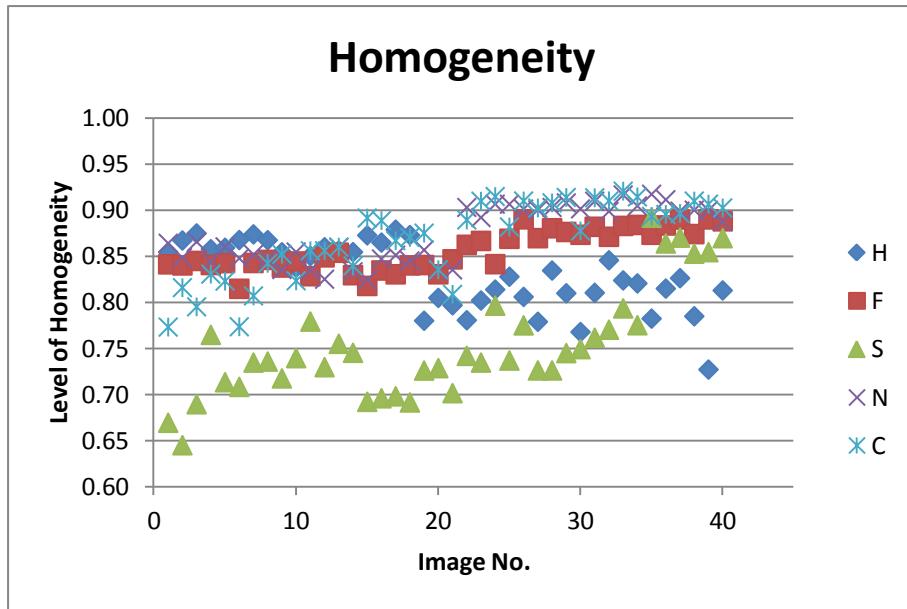

Figure 13: Comparison Chart - 2nd Order Statistics (Homogeneity)

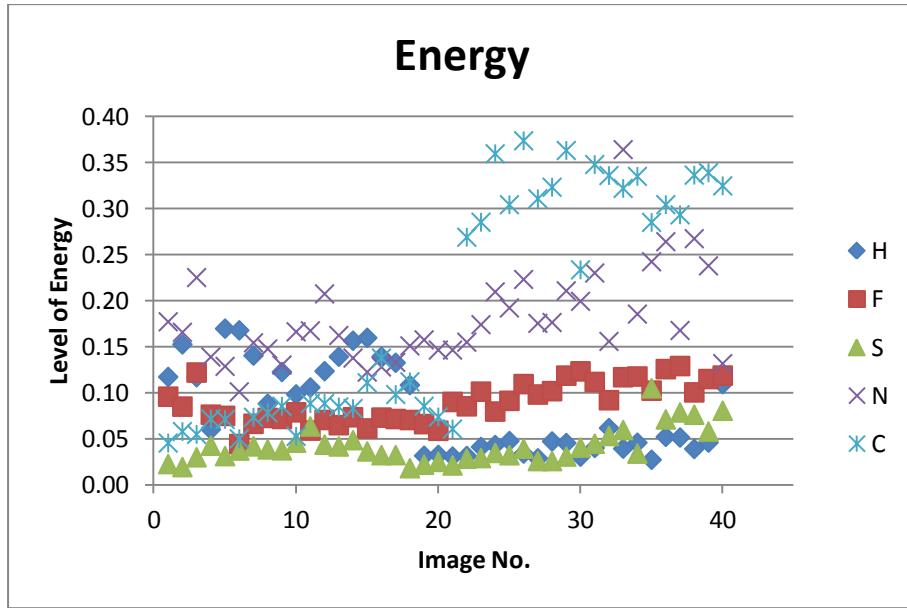

Figure 14: Comparison Chart - 2nd Order Statistics (Energy)

A classification test has been done to check the reliability and accuracy of the features to be used to differentiate the patterns. Variance and correlation features data are not included in the training data for the classifiers. The classification was done using two  $K$ -NN classifier and ADABoost classifier. The accuracy of the  $K$ -NN (44.89%) classifier is better than ADABoost (41.77%). If we observe the accuracy according to pattern types, ADABoost classifier gives the best classification accuracy for nucleolar pattern. However, when it comes to homogeneous,

coarse-speckled, and centromere patterns, the accuracy is significantly low. The accuracy test results are compiled in Table 8 and 9.

Table 8: Percentage of Accuracy based on Patterns

Feature Type	Percent Accuracy (%)					
	Homogeneous	Fine-Speckled	Coarse-Speckled	Nucleolar	Centromere	Overall
<b>1st Order</b>	32.33	34.45	35.56	63.33	37.78	40.69
<b>2nd Order</b>	46.67	76.67	26.67	84.44	61.11	59.11
<b>1st + 2nd Order</b>	31.11	50.00	17.78	63.33	37.78	40.00

Table 9: Percentage of Accuracy based on Classifiers

Classifier Type	Percent Accuracy (%)					
	Homogeneous	Fine-Speckled	Coarse-Speckled	Nucleolar	Centromere	Overall
<b>5-NN</b>	45.56	52.22	28.89	58.89	57.78	48.67
<b>3-NN</b>	52.22	44.45	26.67	56.66	61.11	48.22
<b>ADABoost</b>	12.22	64.44	24.45	95.56	17.78	42.89

## **CHAPTER 5**

### **CONCLUSION AND RECOMMENDATION**

#### **5.1.Conclusion**

From the result obtained, it is clear that the homogeneity and correlation of the patterns are relatively the same. Therefore we must avoid using these features alone to differentiate the patterns as it might give wrong classification information. It is significant that coarse-speckled pattern have more independent values of each features with less overlap with other patterns.

To conclude the current progress, it shows that not every feature extracted from the GLCM analysis can be used to differentiate HEp-2 cell patterns. More texture features are suggested to be explored as in [9] to get more texture information from the image and gain more properties to be used as input to the classifier. Nevertheless, more types of classifier should be tested to get a better classification of the patterns. Further analysis needs to be done in order to make use of the GLCM values to differentiate both patterns. Other statistical method might also be used to observe if it can produce some significant values to be used as differentiator.

#### **5.2.Future Works and Recommendations**

Finally, for the next stage, it is suggested to make use and compare other texture features function as stated in [9] to get more comparable data. Some of the listed functions in [9] is the same as in MATLAB function, but most of other functions are still not made available in MATLAB for direct function call as it is still under improvement. Therefore it will benefit the medical industry if it can be verified to be used for more classification vectors.
