#### Abstract

The knowledge of gas liquid mixing is a vital part of chemical engineering discipline. The application of gas liquid dispersion is widely practiced in the industries nowadays where the gas liquid mass transfer rate is the main interest in the process. In order to enhance the mass transfer the volumetric mass transfer, the stirred tank contactor vessel is used in the industries as well as in the lab. However a problem arise when the parameters that affect the rate of mass transfer is not well studied and understood which can lead to bad operation of the gas liquid mass transfer in stirred contactor.

Prior to the problem, three main parameters affecting the volumetric mass transfer in the gas liquid stirred contactor will be studied which is the impeller speeds and the flow rate of the gas flowing into the vessel. The proposed experiment will be conducted by varying the operating parameters. In studying the effect of gas flow rate to the mass transfer rate, the impeller speed and the power of the impeller is treated as the fixed variables and vice versa.

## ACKNOWLEDGEMENT

First and foremost, I would like to express my greatest gratitude to God the Almighty, of whom without, I would not have the wisdom, ability and strength to carry out this entire Final Year Project.

My highest appreciation goes to my supervisor, Dr. Bawadi Abdullah for his endless guidance and support in assisting me throughout the Final Year Project. The objectives of this project would not have been achieved completely in time without his guidance.

Besides, I also extend my appreciation to Prof. Duvurri Subbarao for assisting me throughout the whole period of projects, especially in understanding the theoretical aspect of my project. Additionally, I would also like to thank lab technicians who have been very cooperative throughout the course of my work. This research project would not have been possible without the facilities provided by Universiti Teknologi PETRONAS.

Apart from that, token of appreciation also expressed to my family and fellow friends for their continuous support from the beginning until the end of this research project. Last but not least, special thanks to those who directly or indirectly involved throughout the completion of this project research.

## Thank you.

## ABBREVIATION AND NOMENCLATURE

$\mathrm{a}=$ mass transfer interfacial area $\left(\mathrm{m}^{2} / \mathrm{m}^{3}\right)$
$\mathrm{C}_{\text {air }}=$ Maximum oxygen concentration in liquid $(\mathrm{mg} / \mathrm{L})$ or $\left(\mathrm{mg} / \mathrm{m}^{3}\right)$
$\mathrm{C}_{\mathrm{i}}=$ Initial oxygen concentration in liquid $(\mathrm{mg} / \mathrm{L})$ or $\left(\mathrm{mg} / \mathrm{m}^{3}\right)$
$\mathrm{C}_{\mathrm{o}}=$ Initial concentration of the oxygen in the gas $(\mathrm{mg} / \mathrm{L})$ or $\left(\mathrm{mg} / \mathrm{m}^{3}\right)$
$\mathrm{C}_{\mathrm{L}}=$ Equilibrium concentration in the liquid

C1=Impeller tip speed constant.
$\mathrm{D}=$ Diameter of impeller (cm)
$D_{b}=$ Diameter of the bubble $(\mathrm{cm})$
$\xi=$ Gas hold up
$\mathrm{k}_{\mathrm{G}} \mathrm{a}=$ Mass transfer coefficient of the gas, $\mathrm{k}_{\mathrm{G}} \mathrm{a}$
$\mathrm{k}_{\mathrm{L}} \mathrm{a}=$ Mass transfer coefficient of air to liquid
$\mathrm{N}=$ Impeller speed (rpm or rps)
$\mathrm{N}=$ Mass transfer rate(mol/second)
$\mathrm{ND}=$ impeller tip speed ( $\mathrm{cm} / \mathrm{s}$ )
$\mathrm{N}_{\mathrm{C}}=$ Critical impeller speed (rpm)
$\mathrm{Q}_{\mathrm{g}}=\mathrm{Gas} /$ air flow rate( $\mathrm{L} / \mathrm{min}$ )
$\mathrm{T}=$ diameter of the vessel $(\mathrm{cm})$
$\mathrm{V}=$ Volume of liquid $\left(\mathrm{cm}^{3}\right)$

## 1. INTRODUCTION

### 1.1 Background of Study

This research paper is basically related to the gas liquid mass transfer in the stirred vessel system. The gas to liquid mass transfer is one of the applications which are mostly used in many processes in industries. Among the industries that implement the concept of gas to liquid mass transfer include the food and petrochemical industries. In order to evaluate the rate of mass transfer the value of volumetric mass transfer coefficient, $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ need to be calculated. The purpose of this experiment is to study the effect of the operating parameter to the $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ values in the stirred gas liquid contactor. The experiment will be conducted using the stirred contactor of diameter, T 28.5 cm and 6 cm diameter of the impeller, D . The parameters that will be tested as the variables which is 1) The effect of gas flow rate 2) The effect of impeller speed

### 1.2 Problem Statement.

One of the important elements of the chemical engineering operation is the application of gas liquid mixing. Several major industrial operations like oxidation hydrogenation and biological fermentation, adopt the application of gas liquid mass transfer (Harnby et al., 1985).Prior to that a study of the mass transfer in stirred gas liquid contactor should be performed in order to provide a better understanding on the mixing and dispersion of gas into liquid. Without a good understanding of the process it will lead to the poor operation of the industrial operation and the opportunity to optimize the mass transfer will be lost. Most of the time the practice of mixing operation is multi-faceted where the agitator is used to perform many critical task in the fermenter operation. Hence It is important for the process engineer to take account all the factor affected by stirring in fermenters, which include the oxygen transfer, surface cooling , air dispersion power drawn as a result of aeration as well as biological stability (Harnby et al., 1985).In this proposal the agitation speed, power and gas flow rate is studied in order to understand its effect on the mass transfer.

### 1.3 Objective

The objective of the research paper is to study the mass transfer rate of the stirred gasliquid contactor and how it will be affected by several operating parameter which include, the frequency of the impeller stirring speed, $\mathrm{N}(1 / \mathrm{s})$ and the gas flow rate $\mathrm{Q}_{\mathrm{g}}(\mathrm{L} / \mathrm{min})$. In order to run this research, an experiment will be conducted. The contacting vessel is used where the gas is introduced at the bottom to form bubble in the vessel. The mean diameter of the bubble is one of the factor that will affect the gas liquid interfacial area per unit volume $\mathrm{a},\left(\mathrm{m}^{2} / \mathrm{m}^{3}\right)$ as well as the gas hold up that will be further discussed in the literature review. It is desirable to have a smaller diameter of the bubble upon contact in the vessel as it can significantly increase the gas-liquid interfacial area per unit volume; a. Gathering information on the characteristic of the bubble in the bubble column is a vital step as the performance of the stirred gas liquid contactor depend on the size of the bubbles, rising velocity of the bubble as well as the velocity profile of the bubble (Shah et al., 1982).

### 1.4 Scope of Study

In this experiment the air-water system will be used to study the gas-liquid mass transfer. Water will be used as the contactor liquid and the air as the gas where the air will be drawn into the vessel using the air compressor.

The scope of the research is to find the effect of the following variables to the $\mathrm{K}_{\mathrm{L}} \mathrm{a}$ values:

1. Stirring speed,N(rpm)
2. Gas flow rate., $\mathrm{Q}_{\mathrm{g}}$ (Liter/m)

## 2. LITERATURE REVIEW

### 2.1 Stirred Tank Gas Liquid Contactor

Stirred gas-liquid contactor is a vessel which is used to provide a contact between the gas and the liquid in order to serve as a medium to provide the mass transfer. The gas will be withdrawn into the contactor vessel through the vessel from the bottom of the contactor. According to Treyball(1980) the best method to operate the gas liquid contactor vessel is by sparging the gas below the impeller at the bottom of the vessel using a ring shaped sparger where it has the same or smaller diameter with the diameter of the impeller used in the vessel and the hole should be provided at the top of the contactor vessel. When the time of between the gas bubbles and liquid is relatively large, deep vessel is preferably used. Meanwhile in order to maintain a large interfacial area for the gas to liquid mass transfer, multiple impellers are used to redisperse gas bubbles as a result of the bubbles coalescence. The interfacial area which is denoted by the symbol a in this proposal is basically evaluated per unit volume and the unit for it is $\mathrm{m}^{2} / \mathrm{m}^{3}$. It will be further discussed and derived in the theory of the literature review. The value of the volumetric mass transfer coefficient is the variable that is going to be calculated in the gas-liquid mixing process.

Besides that in the operation of processiing plant in every part of chemical industry, where the mixing process play an important role, the mechanically agitated contactors are the vital equipment for the operation. In analyzing the literature of characteristic and performance of the ga sliquid contactor,a significant data can be found.In many application of gas liquid mixing nowadays,gas liquid contacting vessel with six blade Rushton disc turbine, gas sparger, and four baffles is usually used but in the term of power consumption and top to bottom mixing these contactors have some disadvantages where high power consumption is required and the top to bottom mixing are poor (Jafari and Mohammadzadeh, 2004).In the other study it is found that the industry frequently use the mechanically agitated aerated vessels for the purpose of gas
liquid mixing. Multiple impeller contactors is able to utilize higher mass transfer rate and because of the reason it is more widely used. Besides that the parameters like power consumption, gas hold-up, dispersion mixing intensity and volumetric mass transfer coefficient is required to design the stirred gas liquid contactor vessel (Moucha et al., 2003).

### 2.2 Previous Study

In conducting this project it is important to refer previous studies regarding the gas liquid contactor done by the previous researchers in order to grasp a better understanding on the principle of gas liquid contactor. As examples Brown et al., have studied the liquid phase mixing model for the stirred gas liquid contactor while Koetsier et al., have studied the mass transfer rate in a closed stirred tank gas liquid contactor. In studying the gas liquid contactor system, it is important to consider the effect of the impeller on the gas liquid mixing .The research on the multistage agitated contactor with the co-current air flow where the gas hold up and liquid phase mixing have been done (Zhang et al., 2006). Besides that a scale up study for various impeller types in multiple impeller system have been performed where the volumetric mass transfer coefficient is the main parameter of interest (Labik et al., 2014). Other than that the power of the impeller is also one of the factors affecting the effectiveness of the gas and liquid mixing process and the design of the multi impeller system based on the power and mass transfer correlation have been presented (Linek et al., 2012).

### 2.3 Mass Transfer Theory

Based on the principle of the mass transfer, the mass transfer rate, N (mole/second) is equal to the value of the mass transfer coefficient; k ( $\mathrm{m} /$ second) multiplied by the variables value of interfacial area of the gas bubbles, $a\left(\mathrm{~m}^{2} / \mathrm{m}^{3}\right)$, the volume of the liquid
$\mathrm{V}\left(\mathrm{m}^{3}\right)$ and the difference between the gas and liquid concentration. The equation is denoted by the following formula:
$\mathrm{N}=\mathrm{k}_{\mathrm{L}} \mathrm{aV}\left(\mathrm{C}_{\mathrm{o}}-\mathrm{C}_{\mathrm{L}}\right)$
$\mathrm{C}_{0}$ is basically the initial concentration of the oxygen in the gas and $\mathrm{C}_{\mathrm{L}}$ is the equilibrium concentration in the liquid. Originally the film theory suggests that there are two transfer coefficient involved in the gas to liquid mass transfer which is:

- Mass transfer coefficient of liquid, $\mathrm{k}_{\mathrm{L}} \mathrm{a}$
- Mass transfer coefficient of the gas, $\mathrm{k}_{\mathrm{G}} \mathrm{a}$

However the mass transfer coefficient of the gas is ignored in the calculation as the gas phase has a high diffusivities compare to the liquid phase.

### 2.31 Gas Bubbles Interfacial Area

The interested variable which is the gas liquid interfacial area a is will determine the $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ value. The value of a is affected by 2 parameters which is

- The gas hold
- Mean diameter of the bubbles, $\mathrm{D}_{\mathrm{b}}$

The parameters like power consumption, gas hold-up, dispersion mixing intensity and volumetric mass transfer coefficient is crucial to design the stirred gas liquid contactor vessel (Moucha et al., 2003).The following shows the equation for interfacial area, a. The interfacial are $a$, is defined by the gas-interfacial area $\left(\mathrm{m}^{2}\right)$ per unit liquid volume $\left(\mathrm{m}^{3}\right)$ which can be written as:

$$
\begin{equation*}
a=\frac{6}{D b} * \xi g \tag{2}
\end{equation*}
$$

From the equation a new term $\xi_{\mathrm{g}}$ is introduced. The term $\xi_{\mathrm{g}}$ is basically the gas hold up which is the volume of bubbles per volume of liquid. The technique to measure the gas hold up will be further discuss in the measurement techniques in this literature review section. Based on the derivation of the equation 2.20 it can be shown the interfacial area is the function of the mean diameter of the bubbles and the gas hold up. The main of the project is to improve the interfacial which will determine the rate of mass transfer as the
value of $\mathrm{k}_{\mathrm{L}}$ is constant based on the equation 2.10. In order to increase the interfacial area, the value of the gas hold up should be increase. The value of the gas hold up itself is the indicator of the mass transfer between the gas and the liquid. Meanwhile the other contributing factor which is the mean diameter of the bubbles $D_{b}$, should be decreased based on the derived equation 2.20 in order to increase the interfacial area and hence increase the mass transfer. For this purpose small and dispersed bubbles is desired and this is why the impeller blade is needed in order to stir the mixture and ensure the mixing of gas and liquid takes place in the contactor.

### 2.4 Measurement Techniques

### 2.41 Measurement of $\mathbf{K}_{\mathbf{L}} \mathbf{a}$

The used of right technique in the evaluation of $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ is important in order to ensure the accuracy of the data obtained in the experiment. In order to choose the technique to be used many factors should be considered which is not the only the accuracy of the technique but also the cost and accessibility of the equipment. To ensure the accuracy of the experimental data obtained in calculating the value of volumetric mass transfer coefficient the suitable technique must be applied in calculating the value of volumetric mass transfer coefficient. Basically There are two types of techniques in the measurement of the volumetric mass transfer coefficient kLa which are the steady state and dynamic technique. the absorbed gas component has to be constantly removed from the liquid phase in the steady state operation techniques .In order to maintain significant concentration difference of the absorbing agent between the gas and the liquid phase it is vital to ensure that the gas removal is fast enough and by using physical desorption or with the assist of chemical reaction, the absorbed gas component can be removed from the system (Baier, 2001).Besides that simulation work has also been done in order to evaluate the volumetric mass transfer coefficient $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ value. In the simulation study population balance model (PBM) was solved using quadrature method of moments (QMOM) in order to find the local bubble size distribution. The Higbie penetration theory and the surface renewal model were also used in the estimation of local volumetric mass transfer coefficient (Gimbun et al., 2009).

### 2.42 Measurement of the Bubbles Diameter, $D_{B}$

The measurement of the bubble diameter is necessary in order to find the interfacial area, a based on the equation 2.20 . One of the techniques that can be used for the purpose is by taking of photograph of the bubbles profile. For this proposed experiment, the photo of the bubbles is taken outside of the gas liquid contactor using a camera. The photo will be analyzed in order to obtain the mean diameter of the bubbles.

Besides that, the particle image velocimetry (PIV) was also used in order to take the photograph of the gas-liquid dispersion (Chen and Fan, 1992). The measurement of the interfacial area is also done using light sheet and image analysis (Busciglio et al., 2010).

### 2.43 Measurement of Gas Hold Up, $\zeta \mathrm{g}$.

The gas hold up is also one of the important parameter that determines the interfacial area for mass transfer. By measuring the increase in the liquid level before and after the gas is introduced into the vessel the overall gas hold-up can be easily measured. However for a low gas hold up in the gas liquid system this method is generally not accurate (Busciglio et al., 2010). Recently Particle image velocimetry (PIV) have been used in investigating the turbulence quantities and the flow field in a gas liquid system (Montante et al., 2007) and it also focused on the simultaneous measurement of gas and liquid flow-field quantities with the application of back lighting and macro lenses (Sommerfeld and Broder, 2009). Besides that a new experimental technique to measure the intercept of bubble sizes and its position in the contacting vessel was presented where the application of fluorescent liquid phase excited by a laser sheet was used. The bubbleswhich is intercepted by the laser sheet projected the "shadows" and the image processing algorithm is adopted for the automatic recognition of the "shadows" projected (Busciglio et al., 2010). In general there are many techniques recently used by the previous researches in determining the gas hold up, however each techniques and procedure used in the evaluation of the bubbles has its own advantages and disadvantages. For example the presence of the probe will affect the flow field in the gas liquid contacting vessel and longer experiment time is required to acquire the data distribution over the entire system. Other than that the coalescence behavior of the
system and the dispersion properties is affected by the use of chemical in measuring the gas liquid interfacial area (Busciglio et al., 2010).

### 3.4 Experiment Methodology

### 3.41 Tools and equipment

For the mass transfer in stirred gas liquid contactor, the essential part of the equipment is the contacting vessel. In this proposed experiment. Common shafts will be used for the vessels. For the laboratory scaled vessel the single Rushton turbine impeller will be used where inner diameter $\mathrm{T}=28.4 \mathrm{~cm}$ and the diameter of the impeller blade is D is 6 cm .

A compressor is equipped in order to enable the air flow into the vessel through the gas sparger and a gas flow rate controller will be used in order to regulate the flow rate of the gas. Besides that the flow rate of the air can be read from the air flow meter. Nitrogen also can be used in the proposed experiment for the Oxygen purging purpose (Kapic et al., 2006). DO meter will be used to check the dissolved oxygen concentration in liquid.

### 3.42 Material

The lists of material needed in this process are air(oxygen) and water.

### 3.43 Designed experiment

The experiment is designed by finding the critical impeller speed which will further discussed in result and discussion for every flow rate based on the following table.

TABLE 2. Designed Experiment

| Gas <br> Rate <br> , $\mathrm{Q}_{\mathrm{g}}($ Liter/min $)$ | 180 rpm | 200 rpm | 220 rpm | 280 rpm | 300 rpm |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 5 | Run 1 | Run 2 | Run 3 | Run 4 | Run 5 |
| 10 | Run 6 | Run 7 | Run 8 | Run 9 | Run 10 |
| 15 | Run 11 | Run 12 | Run 13 | Run 14 | Run 15 |
| 20 | No Run | Run 16 | Run 17 | Run 18 | Run 19 |
| 25 | No Run | No run | Run 20 | Run 21 | Run 22 |

### 3.44 Proposed Experimental Procedure

The experiment is planned to be conducted in batch mode for about 15- 40 minutes depending on the time where the equilibrium mass transfer is achieved(shown by constant dissolved oxygen meter reading) The experiment will be divided into 22 run based on the Table 2.

## Experiment Procedures

1) Turn on the compressor and start the air flow rate into the vessel at the flow of 5 L/minute.
2) The impeller speed is adjusted at the speed of 180 rpm (Run 1)
3) The reading of the dissolved Oxygen meter is taken for every 1 minute until 15 minutes (If the equilibrium Concentration is not achieved in 15 minutes the experiment should be continued until constant Oxygen concentration is achieved.)
4) The experiment is repeated for every run from run to 2 to run 22 with the flowrate and impeller speed to be used is specified in the Table 2.
5) The graph of dissolved oxygen concentration as the function of time is plotted for each of the run to find $\mathrm{k}_{\mathrm{L}}$ a valus.

## 4. RESULT AND DISCUSSION

FIGURE 3. Graph of Gas Flow Rate $\mathrm{Q}_{\mathrm{g}}$ vs Critical Impeller Speed

Before running the experiment the critical impeller speed, $\mathrm{N}_{\mathrm{C}}$ is the parameter that need to be obtained. The graph in Figure 3 shows the correlation between the gas flow rate and the impeller speed. Critical impeller speed in this context refer to the minimum speed in which the Rushton impeller used in the experiment would be able to to break the air bubbles in order to induce mass transfer from oxygen to water. In this project the equation for the minimum impeller speed for system is manage to be obtained by the following equation 3.(The data of the plot is provided in the appendix)
$\mathrm{N}_{\mathrm{C}}=105.97 .19 \mathrm{Q}_{\mathrm{g}}{ }^{0.1991}$

Based on the equation the critical impeller speed is in the exponential function of the gas flow rate and from this equation the experiment is designed by finding the suitable impeller speed to be used for the vessel to ensure the mass transfer is taking place. For instance, the critical impeller speed for 15 Liter/ min air flow rate is 180 rpm . Hence the impeller speed used for $15 \mathrm{~L} / \mathrm{min}$ is 180 rpm and more where $180,200,220$ and 300 rpm
have been used in order to break the bubble. The same methodology is used in designing the impeller speed to be used for other flow rate of the gas. In addition, inside the stirred tank there are 2 main mechanism taking place which is the impeller speed and the air flow rate coming into the tank. If the air flow rate is stronger than the impeller speed used in this system the flooding phenomena will happen. The flooding phenomena refer to the condition in which the speed and power provided to the impeller is not sufficient to break the air bubbles causing the air bubble to rise up without any bubble breakage. Hence mass transfer operation will not happen and flooding phenomena should be avoided by finding the critical impeller speed $\mathrm{N}_{\mathrm{C}}$ which is the basis of designing the experiment. The increase in the dissolved oxygen reading shown by DO meter is noted where it indicate the mass transfer operation is taking place in this experiment. The following table shows the gas flow rate and the respective critical impeller speed which is used in designing this experiment.

TABLE 3. Critical Impeller Speeds

| Gas Flow Rate | Critical Impeller Speed |
| :---: | :---: |
| 5 | 147.5 |
| 10 | 166 |
| 15 | 180 |
| 20 | 190 |
| 25 | 205 |

In defining the critical impeller speed two concepts should be acknowledged which is the gas flow overpower and impeller speed overpower. The gas flow overpower is the condition that must be avoided in the operation of gas liquid mass transfer as in this condition the impeller is overpowered by the gas flow and the bubbles is not dispersed by the impeller. In the other hand the impeller speed overpower is desired in order to break the bubbles and transfer the oxygen into the water.

## Qg vs Gas Hold Up

FIGURE 4. Graph of Gas Flow Rate, $\mathrm{Q}_{\mathrm{g}}$ vs Gas Hold Up, $\xi_{\mathrm{g}}$

After the critical impeller speed is obtained, the experiment is done based on the procedure outlined and the graph of the gas flow rate vs the gas hold up is obtained based on Figure 4 where it is shown that for the impeller speed of 300 rpm will give the highest amount of gas hold up in the vessel compare to other impeller speed and the equation obtained for the gas flow rate in the function of impeller speed for 300 rpm is $\xi_{\mathrm{g}}=0.0958 \mathrm{e}^{0.0414 \mathrm{Qg}}$. Meanwhile for the impeller speed of 280 rpm the value for gas hold up $\xi_{\mathrm{g}}$ obtained increase from $5 \mathrm{~L} / \mathrm{min}$ to 10 and $15 \mathrm{~L} / \mathrm{min}$ before the value drop for the flow rate of 20 and 25 Liter/min. The result obtained for 280 rpm impeller speed is suspected to an error as the pattern of the gas hold up increment is different from other impeller speed where for the impeller speed of 180 to 220 rpm the gas hold up increase with the increment of the air flow rate used in the experiment. Meanwhile the result also show that the lowest impeller speed used which is 180 rpm will induce the least height gas hold up. The explanation for the result is that lower impeller speed will have lower power to break and disperse the bubble inside the tank. Hence, the bubbles are not well dispersed resulting to the lower rate of mass transfer of the oxygen to the water. This is shown by the low value of gas hold up obtained. The equations obtained for the gas hold up in the function of the gas flow rate for each impeller speed are based on the following table.

TABLE 4. Gas Hold Up Correlation

| Impelller speed | Correlation |
| :---: | :---: |
| 180 rpm | $\xi_{\mathrm{g}}=0.0145 \mathrm{e}^{0.0169 \mathrm{Qg}}$ |
| 200 rpm | $\xi_{\mathrm{g}}=0.0251 \mathrm{e}^{0.0722 \mathrm{Qg}}$ |
| 220 rpm | $\xi_{\mathrm{g}}=0.0448 \mathrm{e}^{0.0242 \mathrm{Qg}}$ |
| 280 rpm | $\xi_{\mathrm{g}}=0.16858 \mathrm{e}^{-0.023 \mathrm{Qg}}$ |
| 300 rpm | $\xi_{\mathrm{g}}=0.0958 \mathrm{e}^{0.0414 \mathrm{gg}}$ |

From the correlation obtained gas hold up can be predicted for the any of gas flow rate used in this experiment at the defined impeller speed. The correlation obtained provides a good approach in order to estimate the gas hold up and designing the future experiment in a more systematic way. The following figure shows image of the stirred vessel where the gas hold up at the function of gas flow rate is measured at the tested impeller speed.

FIGURE 5. Image of Stirred Vessel

## 1/ug vs 1 /Gas Hold Up

FIGURE 6. Graph of $1 / \mathrm{ug}(\mathrm{s} / \mathrm{cm})$ vs $1 /$ gas hold up
The next analysis done is this project is the analysis of the graph of $1 / \mathrm{u}_{\mathrm{g}} \mathrm{vs} 1 / \xi_{\mathrm{g}}$ where from the objective of this analysis is to find the slope of the graph.The slope of the graph is obtained from the slope based on the equation proposed by Sable(1993):

$$
\begin{equation*}
\frac{u g}{\xi g}=1+\frac{u b r+u c r-C 1 N D}{u g} \tag{4}
\end{equation*}
$$

Where $u_{\mathrm{g}}=$ velocity of the gas $(\mathrm{cm} / \mathrm{s})$
ubr= buble velocity ( $\mathrm{cm} / \mathrm{s}$ )
$\mathrm{ND}=$ impeller tip speed
$\mathrm{C} 1=$ Constant.

From the slope of the graph the value of ubr+ucr can be obtained where ubr+ucr is the slope of the graph based on the figure 6 where the slope for the 180 rpm impeller speed is $1.7804 \mathrm{~cm} / \mathrm{s}, 200 \mathrm{rpm}$ graph is $1.0133,220$ is 0.8755 , 280 rpm is 0.3864 , and 300 rpm is 0.3163 .

## Qg=5 L/minute

FIGURE 7. Graph of time vs -LN((Cair-C)/(Cair-Cin)) for $5 \mathrm{~L} /$ minute

TABLE 5. $\quad \mathrm{k}_{\mathrm{L}} \mathrm{a}$ values for $\mathrm{Q}_{\mathrm{g}}=5$ Liter/minute

| Impeller speed (rpm) | $\mathrm{k}_{\mathrm{L}} \mathrm{a}(1 /$ minute $)$ |
| :---: | :---: |
| 180 | 0.2257 |
| 200 | 0.1381 |
| 220 | 0.1773 |
| 280 | 0.0972 |
| 300 | 0.0967 |

In order to find $k_{L}$ a value for $Q_{g}=5$ Liter/minute, the graph based on figure 7 is plotted where the slope shows the value of $\mathrm{k}_{\mathrm{L}} \mathrm{a}$.Cair refer to the maximum air concentration, C refer to the instantaneous concentration and Cin refer to initial concentration of oxygen in the air. To verify this the unit of the slope is the same as unit of $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ which is 1 /minute or it can be converted to $1 /$ second. slope obtained is tabulated in Table 5.Based on the table the value of $\mathrm{k}_{\mathrm{L}}$ is highest for impeller speed of 180 rpm , however error is suspected as the value of $\mathrm{k}_{\mathrm{L}}$ a should be higher by using higher impeller speed.. As the impeller speed increase from 200 to 220 rpm , the values of $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ increase while it begin to decrease at the speed of 280 and 300 rpm .

## $Q g=10 \mathrm{~L} / \mathrm{min}$

FIGURE 8. Graph of time vs -LN((Cair-C)/(Cair-Cin)) for $10 \mathrm{~L} /$ minute

Table 6. $\quad k_{L}$ a values for $Q_{g}=10$ Liter/minute

| Speed(rpm) | 180 | 200 | 220 | 280 | 300 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{k}_{\mathrm{L}} \mathrm{a}(1 /$ minute $)$ | 0.109 | 0.0387 | 0.905 | 0.0808 | 0.1466 |

Figure 8 shows the graph plotted between time vs - ln ((Cair-C)/(Cair-Cin))like the previous graph. From the calculation obtained based on Table 6 the value of the slope, $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ is obtained. Based on the result 80 rpm impeller speed shows the highest $\mathrm{k}_{\mathrm{L}}$ a value where error is also suspected as the value of other higher impeller speed should give the higher value of $k_{L} a$. However the pattern is increasing for the value of $k_{L}$ a from 200 rpm to 300 rpm impeller speed from 0.0387 to 0.1466 per minute. This shows a reliable result where increasing impeller speed will give a higher value of mass transfer as based on the literature, the higher speed will have more power to break and disperse the bubbles around the defined volume of the vessel.

## Qg=20 L/minutes

FIGURE 9. Graph of time vs -Ln((Cair-C)/(Cair-Cin)) for $20 \mathrm{~L} /$ minute

Table 7. $\mathrm{k}_{\mathrm{L}}$ a value for $\mathrm{Q}_{\mathrm{g}}=20$ Liter/minute

| Speed(rpm) | 180 | 200 | 220 | 280 | 300 |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |
| $\mathrm{k}_{\mathrm{L}} \mathrm{a}(1 /$ minute $)$ | - | 0.0993 | 0.116 | 0.1323 | 0.1331 |

Figure 9 the Graph of time vs $-\operatorname{Ln}(($ Cair-C)/(Cair-Cin)) for $20 \mathrm{~L} /$ minute where the value of the slope which is $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ is tabulated for the impeller speed in Table 7. The value for 180 rpm is not tabulated as the value of critical speed $\mathrm{N}_{\mathrm{c}}$ for 20 Liter /minute is more than 180 rpm . Hence 180 rpm speed cannot disperse the bubble with this flow rate.From the result obtained in the table it is shown that the result is reliable as the increase in the impeller speed give the higher value of $\mathrm{k}_{\mathrm{L}}$ a from 200 rpm to 300 rpm . For the value of 280 rpm to 300 rpm the value of $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ is quite close and based on the mass transfer theory for the gas-liquid contacting vessel there is some extent where the value of $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ is not increasing with the increase of impeller speed. Hence if more run is conducted, the value offset value for the impeller speed can be obtained. In this experiment, the result for $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ value for $\mathrm{Q}_{\mathrm{g}}=15 \mathrm{Liter} /$ minute and $25 \mathrm{~L} /$ minute is not presented as the result shows many error and cannot be analyzed.

## 5. CONCLUSION AND RECCOMENDATION

As a conclusion, this project is important as it deals with the improvement of the mass transfer rate which can bring a significant impact in the operation of the gas liquid stirred tank. From this experiment, the correlation for the critical gas flow rate vs critical impeller speed manage to be derived for the system of $28.5 \mathrm{~cm} \operatorname{tank} \operatorname{diameter}(\mathrm{~T})$ and 6 cm impeller diameter which is shown by equation 3 .
$\mathrm{N}_{\mathrm{C}}=105.97 .19 \mathrm{Q}_{\mathrm{g}}{ }^{0.1991}$
By obtaining the correlation for the critical impeller speed, the future framework can be designed for this tank in order to run more experiment to increase the effectiveness of the gas liquid mass transfer for this vessel. Besides that, the correlation between the gas hold up and gas flow rate at the function of impeller speed also managed to be derived for the vessel based on the table.

TABLE 4. Gas Hold Up and Gas Flow Rate Correlation

| Impelller speed | Correlation |
| :---: | :---: |
| 180 rpm | $\xi_{\mathrm{g}}=0.0145 \mathrm{e}^{0.0169 \mathrm{Qg}}$ |
| 200 rpm | $\xi_{\mathrm{g}}=0.0251 \mathrm{e}^{0.0722 \mathrm{Qg}}$ |
| 220 rpm | $\xi_{\mathrm{g}}=0.0448 \mathrm{e}^{0.0242 \mathrm{Qg}}$ |
| 280 rpm | $\xi_{\mathrm{g}}=0.16858 \mathrm{e}^{-0.023 \mathrm{Qg}}$ |
| 300 rpm | $\xi_{\mathrm{g}}=0.0958 \mathrm{e}^{0.0414 \mathrm{Qg}}$ |

Based on the correlation obtained the value for the gas hold up can be predicted for any gas flow rate used at the defined impeller speed. Hence by obtaining this correlation, it will also provide a good approach in estimating the gas hold up for the planned future experiment and the method of estimating the parameters to be used for the experiment will be more systematic.

Besides that it can also be concluded that for the gas flow rate $\mathrm{Q}_{\mathrm{g}}$ of 10 liter/ minute increasing the impeller speed from 200 rpm to 300 rpm will give a better $\mathrm{k}_{\mathrm{L}}$ a value while for gas flow rate $\mathrm{Q}_{\mathrm{g}}$ of 20 liter/ minute the same pattern is observed 200 rpm to 300rpm. Other than that the distribution of $\mathrm{k}_{\mathrm{L}}$ a values for the $\mathrm{Q}_{\mathrm{g}}$ of 15 liter/minute and 25 liter/ minute is not able to be presented as there is some error in the result obtained especially the reading of the dissolved oxygen per time. Some of the recommendation for this is to always check and calibrate the dissolved oxygen meter so that the reading shown will be reliable for the analysis of the experiment. The reading obtained from dissolved oxygen meter is important because it will affect the calculation of $\mathrm{k}_{\mathrm{L}} \mathrm{a}$ values. Besides that, the other recommendation for this project is to provide an equipment to measure the gas hold up. This is because the gas hold up is measured by recording the height of the aerated liquid while the liquid level is keep fluctuating. This condition will somehow contribute error to the experiment and an equipment should be installed for the purpose of measuring gas hold up.

Overall, it can be concluded that this work should be continued in order to find the best correlation of the involved parameters in order to achieve the highest value of $\mathrm{k}_{\mathrm{L}}$ a.Besides that, the application of the stirred tank operation parameters is integrated with the knowledge of gas liquid mixing. The project is within capability of a final year student to be executed with the help and guidance. The time frame is also feasible and the project can be completed within the time allocated.
