DEDICATION

My beloved mom and dad

Misalmah Ujang & Raja Shahrom Raja Kamarudin

My supportive husband

Mohd Nor Hilmy Md Dali

My addorable kids

Aimy Delisha & Adib Daniel.

ACKNOWLEDGEMENTS

Alhamdulillah, thank to the Almighty Allah S.W.T for His blessing and for giving me strength and guidance for me to complete this research as my PhD studies. Without His permission, I am not able to complete this research and finished this perfectly. I would like to record my gratitude to my supervisor Assoc. Prof. Dr. Cecilia Devi Wilfred and my co-supervisor Assoc. Prof. Dr. Chong Fai Kait and Prof. Dr. Yatimah Alias (Universiti Malaya) for their supervision and guidance from the very early stage of this research and throughout this PhD journey. It is an exhausting, emotional and struggle journey but somehow this giving me extraordinary experiences throughout the work.

My grateful thank to my beloved family especially my husband Mohd Nor Hilmy bin Md Dali, my daughter Aimy Delisha and my son Adib Daniel. Special dedicated for my mom Misalmah bt Ujang, my dad Raja Shahrom bin Raja Kamarudin, all my family member thank you very much for your prayers, moral support, great sacrifice, patience and encouragement for the completion of this work. Words fail me to express my appreciation to them. Their continuous support, love, confidence, encouragement, passions give me strength to complete this study. It is a pleasure to convey my gratitude to all member Center of Research in Ionic Liquids (CORIL), post doctoral, research officers, friends, students and lecturers. Thank you for their research attitude and consistent guidance throughout this work. Special thanks to our previous post doctoral, Dr Mohd Farid Ismail for his contribution on DFT calculation. To Fundamental and Applied Sciences Department (FASD), Centralized Analytical Laboratory (CAL), Chemical Engineering (CE) staff in UTP, thank you for their kind support for this period and their assistance for analyzing samples. I would like to thank everybody who was important to the successful realization of thesis, as well as expressing my apology that I could not mention personally one by one.

ABSTRACT

The existing processes for CO₂ removal in natural gas is by using alkanolamine which caused several drawbacks *i.e.*, high vapour pressure, corrosive nature and high energy input for regeneration. Therefore a new solvent to replace the alkanolamine is highly needed. Ionic liquids (ILs) are regarded as a potential option because they have negligible vapour pressure under ambient conditions and higher thermal stability. Much higher absorption capacity can be achieved if the CO₂ is chemically absorbed instead of physically. Amino acid have been used as anions due to the functionality of amine group and known as Amino Acid Ionic Liquids (AAILs). However, AAILs suffer the problem of having high viscosities. Amino Acid Polymerized Ionic Liquids (AAPILs), are much easier to handle in solid form with higher CO₂ capacity. In this research, eight different types of amino acids using arginine [Arg], lysine [Lys], histidine [Hist], taurine [Tau], proline [Pro], serine [Ser], alanine [Ala] and glycine [Gly] are synthesized. Different types of cations and alkyl chain length on the cation were also studied. The results showed that the highest CO₂ sorption capacity was obtained with [VBTMA][Arg] with 0.83 mol/mol and this increased to 1.14 mol/mol at 1 atm, 298 K after polymerization. Arginine, [Arg] comprises of multiple numbers of amine, thus accessibility for CO₂ to react with amine is an advantage. By increasing the pressure to 10 bar, the CO₂ sorption increased to 2.77 mol/mol. The sorption decreased at higher temperature and full desorption occurred at 80 °C. The AAPILs also can be reusable with 86 % sorption capacity on fifth sorption. FTIR showed the formation of carbamic acid species after CO₂ sorption, hence proving the chemisorption occurred in AAPILs. From the BET model, it was confirmed that physical adsorption with multilayer formation occurred in AAPILs. Therefore, both chemisorption and physisorption are involved in AAPILs. CO₂ sorption capacity increases gradually with water. The selectivity of AAPILs towards different types of gases showed higher CO₂ sorption capacity with 12.9 wt%

compared to CH₄ (1.3 wt%) and N₂ (0.8 wt%). The degradation temperature and glass transition temperature also increase after polymerization. Four adsorption isotherm models were applied for the CO₂ adsorption *e.g.* Freundlich, Langmuir, Dubinin Raduschkevich and Temkin isotherm. The Freundlich model provides the best fit to the experimental data. The adsorption was also modeled through various kinetic models *e.g.* pseudo first order, pseudo second order, Elovich's kinetic model and an intra-particle diffusion model. It was found that pseudo first order model was well fitted with the kinetic data. Thermodynamic analysis proves that the CO₂ sorption is spontaneous process (ΔG -3.16 kJ/mol) and exothermic in nature with ΔH is -30.3 kJ/mol. According to DFT calculation, CO₂ that attached with one primary amine in arginate shows that ΔH calculated is -30.4 kJ/mol which good agreement with experimental ΔH . This proves it follows 1:1 mechanism. As a conclusion, AAPILs is a good alternative to replace the usage of alkanolamine (0.5 mol/mol) to capture CO₂ in natural gas. The presence of amino acids as anion makes the AAPILs greener and easier to handle. In industry, this will be beneficial due to non volatile, reusable and low energy input for regeneration.

ABSTRAK

Pada masa kini, proses penyingkiran karbon dioksida (CO_2) dalam gas asli adalah dengan menggunakan alkanolamina. Walaubagaimanapun, ianya memberikan beberapa kesan buruk seperti tekanan wap yang tinggi, sifat menghakis dan memerlukan tenaga yang tinggi untuk penggunaan semula. Oleh itu, pelarut terbaru diperlukan bagi menggantikan penggunaan alkanolamina ini. Cecair ionik (ILs) merupakan alternatif terbaru kerana ILs mempunyai sifat tekanan wap yang rendah dan kestabilan terma yang tinggi. Lebih banyak penyerapan CO_2 pada ILs boleh berlaku pada penyerapan kimia berbanding fizikal. Asid amino dipilih sebagai anion dan dikenali sebagai asid amino cecair ionik (AAILs). Walaubagaimanapun, AAILs yang terhasil mempunyai kelikatan yang tinggi oleh itu dengan pempolimeran AAILs dikenali sebagai asid amino polimer cecair ionik (AAPILs), yang bersifat pepejal dan mudah untuk dikendalikan. Lapan jenis asid amino digunakan sebagai anion seperti arginina [Arg], lysina [Lys], histidina [Hist], taurina [Tau], prolina [Pro], serina [Ser], alanina [Ala] dan glysina [Gly]. Jenis kation dan pengaruh panjang rantai alkil juga turut dikaji. Keputusan menunjukkan penyerapan CO_2 yang tertinggi adalah pada [VBTMA][Arg] dengan 0.83 mol/mol dan meningkat pada 1.14 mol/mol setelah dipolimerkan, poly[VBTMA][Arg]. Ini adalah kerana [Arg] mempunyai bilangan kumpulan amino yang banyak oleh itu tindak balas antara CO_2 dan amino adalah tinggi. Apabila tekanan meningkat kepada 10 bar, penyerapan CO_2 juga meningkat kepada 2.77 mol/mol tetapi berkurangan pada suhu setinggi 80 °C apabila terjadi nyahserapan sepenuhnya. AAPILs juga boleh diguna semula dengan peratus penyerapan sebanyak 86% pada penyerapan kali ke 5. Bagi menentukan mekanisme penyerapan, pencirian FTIR menunjukkan wujud kumpulan asid karbamik yang terhasil dari tindak balas CO_2 dan kumpulan amino pada AAPILs yang membuktikan berlakunya penyerapan kimia. BET model pula menunjukkan penyerapan fizikal turut berlaku dengan pembentukan multilapisan pada AAPILs.

Penambahan air pada AAPILs juga menunjukkan penyerapan CO₂ meningkat. AAPILs turut selektif dalam penyerapan gas di mana penyerapan CO₂ adalah tertinggi sebanyak 12 wt% berbanding gas metana (CH₄) (1.3 wt%) dan gas nitrogen (N₂) (0.8 wt%). Kestabilan terma juga menunjukkan suhu degradasi dan suhu peralihan kaca meningkat pada AAPILs. Ini menunjukkan setelah pempolimeran AAPILs berlaku, peningkatan pada penyerapan CO₂ dan kestabilan terma dapat dilihat. Pada tekanan yang tinggi, penyerapan fizikal juga berlaku oleh itu empat isoterma penyerapan dijalankan menggunakan model Freundlich, Langmuir, Dubinin Raduschkevich dan model Temkin. Model Freundlich merupakan model terbaik di mana memberikan pekali regresi terbaik. Kinetik penyerapan CO₂ juga dikaji menggunakan empat model kinetik iaitu pseudo tertib pertama, pseudo tertib kedua, model kinetik Elovich dan model difusi intra-partikel. Daripada pekali regresi, pseudo tertib pertama menunjukkan model kinetik terbaik. Selain itu, analisis termodinamik membuktikan bahawa penyerapan CO₂ adalah secara spontan (ΔG - 3.16 kJ/mol) dan eksotermik dengan ΔH -30.3 kJ/mol. Menurut pengiraan DFT, satu mol CO₂ yang bertindak balas dengan satu mol arginina memberikan pengiraan ΔH sebanyak -30.4 kJ/mol di mana nilai entalpi ini sama dengan nilai entalpi eksperimen lalu membuktikan mekanisma 1:1 tercapai. Kesimpulannya, AAPILs merupakan alternatif terbaik dalam menggantikan penggunaan alkanolamina (0.5 mol/mol). Dengan menggunakan organik asid amino sebagai anion, ILs yang terhasil adalah lebih hijau dan lebih mudah diurus disebabkan oleh AAPILs yang bersifat pepejal. Di industri, ini adalah sangat baik disebabkan oleh sifat AAPILs yang tidak meruap, boleh diguna semula dengan lebih tinggi penyerapan CO₂ dapat dicapai.

LIST OF SYMBOLS

T_g	Glass transition temperature ($^{\circ}\text{C}$)
T_d	Degradation temperature ($^{\circ}\text{C}$)
Z	Compressibility factor (bar.K)
P_{eq}	Pressure equilibrium (bar, atm)
K_L	Langmuir constant (g/mmol)
K_F	Freundlich constant ($\text{mmol}^{1-(1/n)} \cdot \text{g}^{1/n} \cdot \text{g}^{-1}$)
q_m	Maximum adsorption capacity (bar, atm)
q_e	Amount adsorb (mmol/g)
λ	D-R constant (mol^2/J^2)
ω	Polanyi potential
K_T	Temkin constant ($\text{cm}^3/\text{g} \cdot \text{bar}$)
R^2	Correlation coefficient
ΔS	Change of entropy (kJ/mol.K)
ΔH	Change of enthalpy (kJ/mol)
ΔG	Gibbs energy (kJ/mol)
ε	Relative error (%)
q_t	Adsorb capacity at particular time (mmol/g)
K_1	Pseudo first order rate constant (1/min)
K_2	Pseudo second order rate constant (1/min)
α	Initial adsorption rate / polarizabilities (cm^3)
n	Freundlich constant (dimensionless)
R_L	Dimensionless separation factor
β	Extent of surface coverage
σ	Sigma
γ_s^{∞}	Activity coefficient infinite dilution

CHAPTER 1

INTRODUCTION

1.1 Carbon dioxide (CO₂) Removal from Natural Gas

Natural gas is the gas produced from hydrocarbon reservoirs which comes from the reservoir along with the oil. It consists largely of methane (CH₄), ethane (C₂H₆), propane (C₃H₈) and butane (C₄H₁₀), some higher alkanes (C₅H₁₂ and above), nitrogen (N₂), oxygen (O₂), carbon dioxide (CO₂) and hydrogen sulphide (H₂S). It is used as an industrial and domestic fuel, and also used as reactant in chemical synthesis to make carbon black, carbon nanotube and others [1]. Natural gas itself might be considered a very interesting gas because of colorless, shapeless and odourless in its pure form. Natural gas is of great importance not only as a source of energy, but also as a raw material for the petrochemical industry [2]. It is a combustible mixture of hydrocarbon gases and gives off energy when it burned [1, 3].

However, the challenge in natural gas processing is that many raw natural gases are contaminated with undesired components such as H₂S and CO₂ [4]. Therefore, the removal of acid gases (CO₂, H₂S and other sulphur components) is warranted [1, 5]. CO₂, H₂S and any other acid gases must be removed from natural gas because in the presence of water, these impurities can form acids that corrode pipelines and any other components [6]. In addition, CO₂ provides no heating value and must be removed to meet gas quality specifications before distribution to users [4].

In Malaysia, before purification process, the natural gas consists of several gaseous and impurities as shown in Table 1.1. Removal of acid gases from raw natural gas has to be performed not only because of environmental restrictions but also technological problems during gas transportation and commercialization. There are regulation of processing and transportation that requires the removal of these

contaminants [7]. The maximum level of CO₂ in natural gas permitted to customers by pipeline is typically less than 3% although local contracts may stipulate quality specifications different to these values [4]. The captured CO₂ can be pumped back into the reservoir which reduces the atmospheric pollution by impurities like H₂S and the emissions of greenhouse gases as CO₂ [8].

Table 1.1: Chemical compositions in crude natural gas [1]

Chemical Name	Chemical Formula	Percentage (wt %)
Methane	CH ₄	40-50
Ethane	C ₂ H ₆	5-10
Propane	C ₃ H ₈	1-5
Carbon dioxide	CO ₂	20-3
Hydrogen sulphide	H ₂ S	0-1

1.2 CO₂ Emissions

CO₂ emissions from fossil fuel combustion (coal, oil and natural gas) for energy production are also the main source of energy-related emissions [9]. This CO₂ emissions are another economical challenge [10]. Approximately 25% of the total CO₂ emissions in the world are produced from combustion for electricity generation. According to Karadas *et al.* [11], the CO₂ emissions value will increase from 19.4 % in 2005 to 25% in 2030, which is at a rate 2.1% per year due to the combustion of fossil fuel.

Although the characteristics of CO₂ capture from natural gas and from flue gas of conventional fossil fuel fired power plants are very different, it is clear that both problems are closely related. Thus, similar approaches are frequently used for both cases. Therefore, high performance technologies with new cost effective for capturing CO₂ are being researched [6, 8, 9, 12]. The main strategies for natural gas processing are identical to those used in CO₂ capture technologies [7].

1.3 CO₂ Capture Technologies

The current technologies for CO₂ capture and separation mainly include solvents, membrane and sorbents [4]. The mechanism for CO₂ capture depends on the chemistry and the capturing approaches or the absorbent materials [13].

1.3.1 CO₂ removal by amines

Mostly alkanolamines, such as monoethanolamine (MEA), diethanolamine (DEA) and methyldiethanolamine (MDEA) are being used for CO₂ capture through carbamate or carbonate formation. Amines are so effective for CO₂ capture because of their properties such as high reactivity with CO₂, high absorbing capacity (in terms of mass of CO₂) and CO₂ selectivity [14].

The absorption of CO₂ in amine based is mostly acid-base chemistry [5]. Amines readily react with acids to form acid-base salts [15]. This structural characteristic plays the major role in the acid gas removal capabilities of the various amine solvents [3, 16].

Figure 1.1 shows the formation of carbamate species after reaction of amine and CO₂. In Equation 1.1 shows a direct reaction between CO₂ and amine to form zwitterions. These zwitterions react with a base to lose its proton. This base can be any base such as amine, OH⁻ and H₂O as shown in Equation 1.2.

Figure 1.1: Reaction of amine and CO₂

The “carbamate reaction” occurred in Equation 1.2, only occurs with primary and secondary amines. The stoichiometry of the carbamate reaction indicates that 2 mol of

amine react with 1 mol of CO₂. Thus, the capacity of CO₂ captured is limited to 0.5 mol CO₂ per mol amine [8].

However, the carbamate can undergo partial hydrolysis as shown in Equation 1.3 to form bicarbonate and regenerate free amine. Thus, CO₂ loading greater than 0.5 moles is possible through the hydrolysis of the carbamate intermediate to bicarbonate [17].

However, there are drawbacks linked with amines such as high vapour pressure, corrosive in nature and requires high energy input for regeneration. The high vapour pressure allows emission of amine gases into the air upon heating. These gases are unstable in nature thus giving them the possibility of producing dangerous toxins such as nitrosamine, nitramine and amides [18-21]. Nitrosamines are of the most concern as they are cryogenic and toxic to humans even at low levels. The amines itself are also corrosive especially MEA which corrodes the equipment. The regeneration process leads to high energy consumption in order to break the chemical bonds formed between the CO₂ and amine [22]. The intensive energy use to break the chemical bonds between the absorbents and the absorbed CO₂ in the regeneration step is $\Delta H = -80$ to -64 kJ/mol for bicarbonate formation or -101 kJ/mol for carbamate formation. This represents a high operation expense due to the energy cost related to the regeneration step [23].

1.3.2 CO₂ removal by membrane

CO₂ removal from natural gas also uses membranes or a thin barrier that allows passage of certain substances. The membrane acts as a filter to remove one or more gas components from a mixture [6, 24]. Some are used in an industrial scale and have the possibility of being implemented into the process of CO₂ capture [6, 22]. Membrane separation technology is based on the interaction of specific gases with the membrane material by a physical or chemical interaction. Membranes with immobilized amine or alkali carbonate solutions attach to amine functionality can be

classified as a chemical absorption process. By modifying the material, the rate at which the gases pass through can be controlled [22].

There are two characteristics that describe the performance of a membrane which is permeability and selectivity. Permeability is defined as the volume of a gas species passing through the membrane per unit time and area. Selectivity quantifies a membranes preference to pass one gas species over another. This permeability and selectivity of membranes are strongly dependent upon gas stream characteristic (*i.e.* velocity, gas component molecular weight and kinetic diameter) [6]. Figure 1.2 shows a general schematic of a gas separation membrane.

Figure 1.2: Schematic of a gas separation membrane [6].

Gas mixtures can be separated with porous and nonporous membranes. The porous membrane acts as a boundary between gas and liquid, whereby a non-porous membrane allows selective and controlled transfer of a species from one phase to another phase which separated by membrane. By using non porous hollow fibers, the separation is normally regarded as a rate governed membrane separation process. This kind of polymeric membrane requires a pressure upstream for removal efficiency which restricts the application. Meanwhile, for the porous membrane, the driving forces, transport mechanisms, and basis for selectivity reside in the two contacting phases, either liquid/liquid or gas/liquid. The selectivity is governed by the partitioning characteristics between the two phases. Therefore, under certain conditions, the membrane pore size can also influence the solute selectivity [25].

Polymeric membranes generally is non porous and gas permeation is described by the solution diffusion mechanism. This is based on the solubility of specific gases within the membrane and their diffusion through the dense membrane matrix. The separation is not just dependent upon molecular size but also relies on the chemical

interaction between the gases and the polymer [24]. It also exhibit high CO₂ permeability but low selectivity. This can be controlled by altering the pressure, temperature and polymer concentration during membrane synthesis. This polymeric membrane is susceptible to aging, plasticization and degradation at higher temperature [18].

There are variety of polymeric membranes which provide good permeability and selectivity towards CO₂ in CO₂/N₂ gas streams [26]. These includes polyimides, polycarbonates, polyethyleneoxide (PEO), polyacetylenes, polyaniline, poly(arylene ethers), polyarylates, polyphenylene ethers and polysulfone. The CO₂ permeability and selectivity of the most popular polymeric membranes is shown in Table 1.2.

Table 1.2: CO₂ permeability and selectivity of polymeric membranes [6]

Material	CO ₂ permeability (barrer)	CO ₂ /N ₂ selectivity
polyarylate	5-85	10-30
polycarbonate	5-110	15-26
Polyimide	5-450	5-55
polysulfone	5-110	10-33

Generally, polyimide has high permeability and CO₂ selectivity which makes them more attractive as a membrane compared to the others [6].

1.3.3 CO₂ removal by solid sorbents

A variety of materials have been studied as CO₂ sorbents through chemical reactions and physical adsorptions [18]. Aqueous amine solution exhibit disadvantages such as low contact area between gas and liquid, low CO₂ loading and severe adsorbent corrosion. Therefore, solid adsorption process may be an alternative to achieve the CO₂ capture purpose [20]. There are variety of solid adsorbents for CO₂ capture including microporous and mesoporous materials which is carbon-based sorbents such as activated carbon and carbon molecular sieves, zeolites, metal oxides and others.

Carbonaceous adsorbents such as activated carbon have been widely used for CO₂ capture due to their wide availability, low cost, high thermal stability and low

sensitivity to moisture. However, in a range of 50-120 °C, the carbonaceous materials exhibit low selectivity in operation due to high sensitivity in temperature. Studies showed that activated carbon and charcoal were shown to exhibit moderate adsorption selectivity for CO₂/N₂ at low pressures below 1 atm [27].

Zeolites are amongst the most widely reported physical adsorbents for CO₂ capture. It largely affected by their size, charge density and chemical composition of cations in their porous structures [28]. The interaction between CO₂ molecules and modified basic sites are through the formation of covalent bonding [29]. Although CO₂ adsorption can be enhanced by these approaches, there exist several drawbacks. The result showed that the CO₂ adsorption capacity and the CO₂/N₂ selectivity are relatively low. Besides the CO₂ adsorption capacity greatly declines in the presence of moisture in gas because of their highly hydrophilic character, thus a high regeneration temperature (above 300 °C) is needed [30].

Metal oxides (such as CaO and MgO) are promising capture materials given their ability to retain high adsorption capacities at temperatures above 300 °C. This operation defined as carbonation-calcination cycle: the carbonation reaction of CO₂ with solid CaO at 600 – 650 °C precipitates calcium carbonate (CaCO₃), while the reverse calcinations reaction regenerates the oxide at 800 – 850 °C [31]. However, the degradation of adsorbents has been observed after several cycles. To improve oxide materials, metals containing lithium such as Li₂ZrO₃ and Li₄SiO₄ have recently attracted attention for their high CO₂ adsorption capacities [32].

Metal-organic frameworks (MOFs) also have attracted significant interest in the recent years due to their remarkably high surface area, controllable pore structures and tunable pore surface properties. These properties can be easily tuned by changing the metallic clusters or the organic ligands. MOFs exhibit exceptional CO₂ adsorption capacity to deal with pure CO₂ at high pressures. However, their adsorption capacities are dramatically reduced when they are exposed to a gas mixture [33]. Although carbonaceous and MOFs materials seem to be as promising CO₂ adsorbents, the operations are at high pressures and low temperatures. It also showed that low selectivity is the major drawback for most physical adsorbents.

1.4 Ionic Liquids (ILs)

Ionic liquids (ILs) are a new class purely ionic salt-like materials that are liquid at room temperature with a low melting point (below 100 °C) are commonly composed of ions with combinations of organic cations and organic / inorganic anions. Therefore, ILs have been highly promoted as “*designer solvents*” as they can be designed by appropriate combinations of various cations and anions which increases their potential applications [34]. Over the last few years, ILs have been popularly used as solvents for organic synthesis and also been used as media for extraction processes and also known as greener solvents as they will replace volatile organic solvents in several chemical reactions [35, 36].

The first ionic liquid was discovered during World War I, in 1914, in the field of explosives research. It was ethylammonium nitrate with a melting point of 12 °C [37]. Nowadays, around 10^{18} ILs have been predicted and could be synthesized by combining different ions [38].

Chemically, the ionic liquids are composed of an organic asymmetric cation such as imidazolium, ammonium, phosphonium, or pyridinium species with one or more alkyl groups attached to the nitrogen or carbon atoms [39]. The most employed anions which influence the ionic liquids properties commonly used halides, mineral acid anions, and polyatomic inorganics species like PF_6^- , BF_4^- [40] as shown in Figure 1.3.

Figure 1.3: Cations and anions usually used in ionic liquids synthesis

The physical and chemical properties of the ionic liquids are determined by the nature of cation and anion. Therefore it is possible to achieve specific chemical properties by tuning the combinations of cations and anions [41]. Some properties such as thermal stability and miscibility depend on the anion while others such as viscosities, surface tension and density depend on the alkyl chain in the cation and/or shape or symmetry [42].

The use of ILs to replace conventional materials has received considerable attention as they are potentially safer and cleaner due to their extremely low vapor pressure, if the ionic liquids are properly chosen [43]. ILs have been extensively studied in different areas such as batteries [44, 45], green solvents [46, 47], CO₂ capture [48, 49], biopolymer dissolution [50-54] and others applications such as [42] liquid-liquid extraction [55, 56] or in membrane separations [57-59].

1.5 Ionic Liquids (ILs) for CO₂ capture

Among the many potential absorbents studied, ILs are regarded as a potential option for CO₂ capture because they typically have negligible vapour pressure under ambient conditions [60, 61]. The physico-chemical properties such as viscosity and density can usually be tuned to suit the intended use [21].

There are a large number of experimental studies on ILs for CO₂ capture. Brennecke *et al.* [59, 62-64], were the first to report on CO₂ solubility in imidazolium and pyridinium ILs. They found that ILs that contains fluoroalkyl chains on either cation or anion improves CO₂ solubility in contrast to less fluorinated ILs. These fluorinated ILs have high stability and low reactivity and thus have many excellent properties. However, these ILs only applicable for physical adsorption therefore higher pressure needed for capturing CO₂ [59]. Thus, with fluoro groups in ILs, they are poorly biodegradable and less environmentally benign [65].

Much higher absorption capacity can be achieved if the CO₂ is chemically absorbed instead of physically [66]. Bates *et al.* [67] prepared ILs with functionalized amino group tethered at the cation. Thus, the mechanism 2:1 (ILs : CO₂) applied and the maximum CO₂ capacity can be up to 0.5 mol/mol at 1 bar pressure. Goodrich *et al.* [68] suggested that 1:1 (ILs : CO₂) mol ratio can be achieved when the amine is tethered to anion instead of cation. They used amino acid as anion is known as Amino

Acid Ionic Liquids (AAILs) and achieved CO₂ capacity with 1 mol/mol [69-71]. However, these AAILs suffer the problem of having high viscosities since AAILs with amine functionalized either in cation or anion increases the van der Waals interactions, hence increasing the number of hydrogen bonds [72]. This higher viscosities would slow the absorption kinetics and causes higher operational cost [73].

Polymerized ionic liquids (PILs) have recently attracted attention due to the solid material formed after polymerization of ILs. This would overcome the viscosities problem in ILs. PILs also exhibiting higher CO₂ adsorption compared to the monomeric ILs [40, 74-78]. This is because PILs have larger free volume which can trap a larger amount of CO₂. The properties of PILs also can be customized by varying the combination of polycation-anion pair [79]. The capacity of CO₂ capture depends on the type of polycation, polymer backbone, anion and substituents [80]. The polycation type is considered a decisive factor in CO₂ capture performance, with ammonium-based having high CO₂ capacity than imidazolium-based PILs [80, 81]. Most of the PILs reported in literature are using inorganic anions *i.e.* [PF₆] and [BF₄] which make them difficult to be applied to industry [81]. In addition, these PILs only have a physical adsorption with low CO₂ capacity.

1.6 Novelty of Amino Acid Polymerized Ionic Liquids (AAPILs)

ILs with amine functionalized are synthesized by using amino acids as anion which is known as Amino Acid Ionic Liquids (AAILs). These AAILs are expected to give high CO₂ sorption capacity since the functionalized amine would enhance the CO₂ capacity by chemical absorption. By using amino acid with multiple numbers of amine group *i.e* arginine and lysine, it is expected to give higher CO₂ sorption capacity as they are more amines reacting with CO₂.

To overcome the viscosities of AAILs, these AAILs are then subjected to polymerization. These ILs are known as Amino Acid Polymerized Ionic Liquids (AAPILs). The AAPILs are formed in solid where they are much easier to be handled compared in liquid form. The AAPILs are a new type of PILs with amine functionalized tethered to the anion. Chemical absorption are dominant instead of only physical adsorption as other authors reported [74, 75, 82, 83]. Thus, the CO₂

sorption capacities as expected to be higher in AAPILs than in monomeric form, AAILs.

In addition, amino acid is a greener organic anion that replaces the use of inorganic anion in PILs *i.e.* $[\text{PF}_6]$ and $[\text{BF}_4]$ which may form HF gas. Thus, AAPILs would be a potential solvent to replace the alkanolamine which only limited to 0.5 mol/mol.

1.7 Problem Statements

The increasing carbon dioxide (CO_2) content in natural gas reserves discovered around the world is one of the major issues facing the industry nowadays. Therefore, CO_2 must be removed from natural gas in order to increase the heating value of the gas, prevent corrosion of gas process equipment and crystallization of CO_2 during the cryogenic process (liquefaction process) and to meet pipeline specifications. RTILs have been proposed as promising alternative for capturing CO_2 . The common disadvantages for all ILs, is the higher viscosity which slow the adsorption kinetics and causes higher operational cost.

Polymerized ILs, (PILs) which could be formed by polymerizing the ILs monomer, will incorporate macromolecular structure with ILs. This would enhance the CO_2 sorption as compared to monomer ILs. The available data of PILs on CO_2 sorption are basically on $[\text{PF}_6]$ and $[\text{BF}_4]$ based anion polymers which make it difficult to apply in industry as they form toxic HF gas. Although PILs have been known to be used as CO_2 adsorbents, there are some limitations in adsorption capacity seen for PILs. The PILs suffer from relatively low CO_2 adsorption capacities due to physical adsorption mechanism. Therefore, much higher adsorption capacity can be achieved if the CO_2 is chemically absorbed instead of physically [68]. Therefore, by synthesize new AAPILs, a green ILs formed with functionalized amine tethered in anion would expect to give higher CO_2 sorption capacities. This is because, after polymerization the CO_2 sorption capacity increases due to involvement of physical adsorption as well with chemical absorption. In addition, the AAPILs are in solid form thus easier to handle than in liquid form.

1.8 Objectives

The objectives of this study are:

1. To synthesize and characterize Amino Acid Polymerized Ionic Liquids (AAPILs)
2. To study the chemical absorption and physical adsorption in AAPILs for CO₂ sorption
3. To study the effect of amine functionality on amino acid as anions for CO₂ sorption
4. To propose the absorption mechanism between AAPILs and CO₂

1.9 Scope of Studies

The scope of this research is to synthesize and characterize amino acids polymerized ionic liquids (AAPILs) for CO₂ capture. A number of cations (ammonium, piperidinium and imidazolium based) and anions (glycine, alanine, serine, proline, taurine, histidine, lysine and arginine) will be synthesized. The different alkyl chain length on cation (methyl, ethyl and butyl) will also be studied for CO₂ capture.

This study has been divided to four stages. The first is to study the monomer (AAILs) in terms of thermal stability and CO₂ sorption at 1 bar and 298 K. The effect of polymerization on thermal stability is studied between the monomers and polymers.

Secondly, these AAILs will undergo polymerization to form AAPILs. These AAPILs are believed to enhance the CO₂ sorption and thermal stability of the monomer (AAILs). The performance of AAPILs in terms of CO₂ sorption is expected to be improved. The effect of changing the cation and anion will be carried out at 1 bar and 298 K. The screening process was done at ambient pressure to study the mechanism.

Thirdly, the best AAPILs will be subjected to higher pressure (up to 10 bar) and temperature (298 K to 353 K) to study the adsorption and desorption of CO₂. The characterization before and after CO₂ sorption will be studied by using FTIR in order to confirm the chemical absorption occurred in AAPILs. Several amino acids are used to study the effect of amine functionality as anion. This study will proceed with COSMO-RS to study the chemical potential between CO₂ and anions. To confirm the physical adsorption, BET model is carried out to determine the physical adsorption isotherm.

At the fourth stage, is the effectiveness of AAPILs on recyclability, selectivity of gases and addition of water in AAPILs towards CO₂ sorption are determined. Since ILs is known to be expensive, the recyclability of AAPILs is studied. The selectivity of AAPILs with different type of gases (CO₂, methane and nitrogen) would be studied to confirm the separation of gas in natural gas.

Generally, the isotherm and thermodynamic studies on CO₂ absorption are also important to study the enthalpy, entropy, Gibbs energy and activation energy on AAPILs. To confirm the enthalpy in the experimental is same with the calculated enthalpy, the DFT in thermodynamic analysis will be carried out to confirm the reaction between amine with CO₂. Once the reaction between amine and CO₂ is confirmed, the mechanism between AAPILs and CO₂ can be proposed.

1.10 Thesis Outline

Chapter Two is the literature review on the main topic of this thesis. This review includes two parts. First part is related in the field of synthesis, physical properties and thermal stability of ILs. The second part provides a review on related research work in the field on the solubility of CO₂ in RTILs, TSILs and PILs.

Chapter Three is the research experimental and methods. The details on materials and procedure to synthesize AAILs and AAPILs followed by details experimental procedure are explained. All the characterization of these AAILs and AAPILs synthesized is also explained.

Chapter Four presents the results from the characterization of AAILs and AAPILs synthesized. Chapter Four also includes CO₂ sorption of the AAILs and AAPILs and

the effects of: polymerization, changing the anion, cation, alkyl chain length of cation, effect of pressure, BET model, temperature, activity coefficient, adsorption isotherm, kinetic studies, DFT calculation, proposed mechanism, addition of water, selectivity of gas and reusability of AAPILs are also studied. Chapter Five is the conclusion followed by recommendations for future works in AAPILs for CO₂ capture.

CHAPTER 2

LITERATURE REVIEW

This chapter is divided into two main parts. First is the synthesis part which provides a review on related work in the field of synthesis, the physical properties (densities and viscosities) of ILs and thermal stability (decomposition temperature, T_d and glass transition temperature, T_g) of ILs. The second part provides a review on related research work in the solubility of CO₂ in alkanolamine, RTILs, TSILs, AAILs and PILs. The effect of different factors such as alkyl chain length and functional groups, cations and anions, effects on polymerization on the CO₂ sorption is also reported.

2.1 Physical Properties of Ionic Liquids (ILs)

Ionic liquids (ILs) are special salts consist of bulky organic cations and inorganic / organic anions. This ILs are composed entirely of ions and strongly resemble ionic melts that may be produced by heating metallic salts [84]. New ionic solvents could be made by coupling different positive and negative ions for countless reactions. Therefore this led to the possibility of customizing the design of ionic solvents for a specific application. Physical and chemical properties such as density, conductivity, viscosity, lewis acidity, hydrophobicity and hydrogen bonding capability of the ionic solvents can be changed by varying the structure of the component ions to obtain the desired solvent properties [42].

Holbery *et al.* (2003), reported the major factors influencing the low melting point in ILs are charge size, charge distribution of ions and the asymmetric extent of the cation [85]. Generally, larger ions results in a decrease in melting point due to the delocalization of charge, less charge density and therefore reduced Columbic attraction between the ions. The failure of the ions to fit into crystal lattice owing to

the sizes of the ions involved, described as “*packing inefficiency*” has been anticipated as a key factor in rationalizing the low melting points of some ionic liquids [86]. Large anions with many degrees of freedom reduce crystallization until lower melting points are obtained [87].

ILs also can be made up by mixing of acid and base and known as protic ILs. The attentions of protic ILs have been explored since the potential cost is lower. Protic ILs was produced by proton transfer from acid to base. Vijayarhagavan *et al.* (2013), have studied the protic ILs for CO₂ capture [88]. The results showed that the sorption process with protic ILs included a chemical reaction and it is comparable with 30 wt% MEA. However, the mass transfer coefficient magnitudes lower than MEA which is might be due to the higher viscosity of ILs and its impact on CO₂ diffusivity. Thus it is explain that the viscosity of ILs gives major impact on the CO₂ sorption capacity.

Amino acids have both a carboxylic acid residue and an amine group in a single molecule; therefore, they can be used as either anions or cations. These groups are useful in their ability to introduce functional groups to the ILs. The properties of the resulting AAILs depend on the side groups of the amino acids involved. The advantages by using amino acids are their low cost, high biodegradability and high biological activity. Since the AA contains both an amino group and carboxylic acid in a single molecule, with various side groups and a chiral carbon atom, AAs are the best candidates to act as a platform for functional ILs as shown in Figure 2.1 [73]. However, with this functionalized groups, the AAILs suffer the problem of having high viscosity as they have larger van der Waals force and a tendency of forming numbers of hydrogen bonds.

Figure 2.1: Design of amino acids for functionalised ILs

However, this ILs can be proposed as hydrophilic or hydrophobic ILs by tailoring the cation and anion. Usually the hydrophobic ILs reported as replacements for hydrophobic organic solvents. Hydrophobic ILs, mostly contains fluorinated anions such as hexafluorophosphate, PF_6^- or bis(trifluoromethylsulfonyl)imide, Tf_2N^- . This is because fluorine would weaken the electrostatic interaction force through a reduction of anionic charge density thus making this salt hydrophobic [89]. These hydrophobic ILs generally undergo phase separation with water which provides a liquid-liquid extraction system as well as yielding heterogeneous reaction media.

Since tendency of functional groups in amino acid to make a hydrogen bond with water is higher, Kagimoto *et al.* [90], worked on synthesized hydrophobic AAILs. It were first prepared by Fukumoto and Ohno [72] by using 1-ethyl-3-methylimidazolium as cation, ([emim]) with 20 different natural amino acids as anion. However, [emim][AA]s showed a decomposition temperature around 200 °C. To overcome this, Kagimoto *et al.* [90] used phosphonium cations because of good thermal stability and electrochemical thermal stability. They synthesized a series of AAILs ($[\text{P}_{n,n,n,m}][\text{AA}]$) with $n \geq 6$, showed a hydrophobic ILs and underwent phase separation with water. The results also showed that water content in the ILs depended on the amino acid side chains and the alkyl chain length of the cation [91].

To study the densities in AAILs, Kagimoto *et al.* [90], reported that the density depends mainly on the number of carbon atoms, regardless the symmetry of the cations. The density decreased with increasing alkyl chain length or having only an alkyl group on the side chain length on the amino acids. This is because the elongation the alkyl side chains of $[\text{AA}]^-$ increases the free volume of the ILs thereby decreasing the density [71]. However, with introduction of functional groups including the carboxyl group, hydroxyl group and aromatic ring, the density of salts increases through effects the hydrogen bonding and π - π stacking. This agrees with Zhang *et al.* [71] showed $[\text{AA}]^-$ with grafting functional group increases the densities than *n*-alkyl chains [71].

The amine-functionalized ILs especially tertiary amine-functionalized ILs has lower densities compared to the non-functionalized ILs [92]. The density of the ILs depends also on several factors such as electrostatic interactions between positive and negative, molecular mass, size and shape (symmetry) of the ions and on the dispersion forces or van der Waals forces of attraction between molecules. By changing the alkyl

chain length, the density of ILs can be controlled. The combination of cation and anion need to be careful because some properties *i.e.* density, viscosity and hydrophilicity are affected by the alkyl groups of ions [93-95]. This is supported by Goodrich *et al.* [96] that increasing the alkyl chain length on either cation or anion, the density will decrease. They synthesized AAILs with [P₆₆₆₁₄] as cation and amino acids as anion. The density was observed to decrease in the order [Gly] > [Ala] > [Sar] > [Val] > [Leu] > [Ile].

For the dicationic ILs, their densities were observed to increase linearly with a decrease in temperature and higher than the density of water and traditional solvents. The densities of AA-DILs were higher than AAILs phosphonium based but lower than amine functionalized imidazolium type ILs and traditional-DILs. The densities of [bis(mim)C₆][Tf₂N]₂ are higher than [N₁₁₁-C₆-mim][Tf₂N]₂ due to the symmetrical DIL which had a higher density than their asymmetrical analogs due to symmetry effects in its molecular structure [97].

However the main problem with ILs, it suffers a problem of having high viscosities due to nature of liquids. The viscosity of AAILs mainly depends by the strength of both the van der Waals interaction force and hydrogen bonding. Generally, the viscosity increases with elongation of the alkyl chains [90]. According to Zhang *et al.* (2009), by tethering dual amine groups in cation and anion, the viscosities of the [aP₄₄₄₃][AA] are large mainly because the larger size of [aP₄₄₄₃]⁺ leads to increasing number of van der Waals interactions [71]. Two amine groups may increase the number of hydrogen bonds. By increasing the chain length of [AA]⁻ it decreases the mobility of the ionic liquids leading to an increase of viscosities as follows [Gly] < [Ala] < [Val] < [Leu] (713.9 < 758.0 < 888.2 < 1193.8 mPa s at 25 °C). The presence of large ring in the [AA]⁻ anion also decreases the mobility of the ILs leading to increase in the viscosities such as [Trp]⁻, [Tyr]⁻ and [His]⁻ are all above 2000 mPa s at 25 °C. The grafting of an SH or OH functional group onto the [AA]⁻ anion increases the viscosity due to tendency to form hydrogen bonds for example [Cys]⁻, [Ser]⁻ and [Thr]⁻ compared to [AA]⁻ without functional group.

It was well known that the viscosities of traditional monocationic ILs were usually low especially when pairing with [Tf₂N], [PF₆] or [TfO] anion. However, when introducing amine groups onto the cation or anion, the viscosities increase with nearly four times. For dicationic ILs (DIL), the viscosities of [bis(mim)C₂][Gly]₂ was 2586

cP at 30 °C which was the lowest for DIL, but still higher than some monocationic functionalized counterparts. Furthermore, the viscosities of DILs were largely dependence on their molecule structures. The longer alkyl side chain of the amino acids and alkyl link-chain of the dication, the higher their viscosities became [97].

This is supports by Muhammad *et al.* (2011), that the structures of AA anions have pronounced effect on the viscosities of the AAILs [98]. This might be because of the increase in the internal resistance, for mobility of the AAILs. The functional group in AA anions also contributes to the increases of viscosity of AAILs due to its tendency to form hydrogen bonds. The interaction such as hydrogen bonding, van der Waals interactions and size of amino acids were found to increase following the order [emim][gly] < [emim][ala] < [emim][ser] < [emim][pro].

Therefore, due to their liquid nature, ILs lack mechanical stability and may not be able for certain application when a solid material is needed. Poly ionic liquids (PILs) which is in solid form is one of the alternatives to overcome the viscosity problem in ILs. PILs is a species with monomer repeating unit connected through a polymeric backbone to form a macromolecular architecture [83]. The properties of PILs are strongly related to both polymer backbone and ILs structure. The structure of the cation and anion (ion type and substitute groups on cation) determine the physicochemical properties of ILs. Unlike the ILs or ILs/polymer mixture, where both cation and anion are mobile, PILs are restricted in mobility compared to their counter ions [99].

The major advantages by forming PILs are easier to handle, enhanced stability, improved processability, flexibility, durability to improve control over meso to nano structure. PILs can be prepared by polymerization of cation or anion which resulting in macromolecular with repeating charge (cationic or anionic) units. Two common groups being examined when approaching for the preparation of PILs are acryloyl (or methacryloyl) and vinyl groups [40].

2.1.1 Thermal properties of ILs

The studies of thermal stability of ILs are needed to ensure the stability of ILs for capturing CO₂ at higher temperature. Kagimoto *et al.* (2010), reported that for symmetric cations, the glass transition temperature (T_g) decreased with increasing

alkyl chain length up to carbon number 8, [P_{8,8,8,8}] [90]. This reduction in T_g has been attributed to the disruption of crystal packing and the flexibility increase due to alkyl chains and also reduction in lattice energy. However, the T_g increases again when $n=10$ due to increase in van der Waals interaction force. The T_g of AAILs with long alkyl chain depends more on the flexibility of the alkyl chain rather than the side chain structure of the amino acids [90].

ILs thermal stability is ruled by intermolecular interactions. The three most important ones are hydrogen bond, Coulombic interactions (occurred between anionic and cationic charges) and van der Waals interactions. However the degradation temperature (T_d) decreases with substitution of the alkyl chain where it induces a higher molecular volume of the cation and also the presence of fluorine atom [100].

AAILs with phosphonium cation have greater thermal stability than other AAILs by different cations. It is suggested that dealkylation of the cation took place during the thermal decomposition. The results also showed that the T_d of AAILs-imidazolium based is lower than corresponding amino acids. For example the decomposition temperature of [emim][Ala] is 212 °C and alanine is 297 °C. However, for phosphonium cation with alanine as anion, the decomposition temperature is 288 °C. These is clear that the cations decompose before amino acids [90]. According to Zhang *et al.* (2009), ionic liquids with [aP₄₄₄₃][AA] have glass transition temperature from -69.7 to -29.6 °C, lower than those of [emim][AA] [71]. For example the differences of T_g between anions of [Asp], [Gln], [Glu] and [Arg] from [emim][AA] and [aP₄₄₄₃][AA] are 58.9, 40.4, 40.3 and 38.3 °C, respectively.

As well as the cation [aP₄₄₄₃]⁺, the structures of [AA]⁻ also have a big effect on the T_g and T_d values. The T_g values decrease in the order [aP₄₄₄₃][Gly] (-69.7 °C) < [aP₄₄₄₃][Ala] (-67.3 °C) < [aP₄₄₄₃][Val] (-62.5 °C) < [aP₄₄₄₃][Leu] (-61.4 °C) which corresponds to an increasing length of the alkyl side chain of the [AA]⁻. For thermal decomposition, the active functional groups on [AA]⁻ and the high negative charge density of [AA]⁻ lower the thermal decomposition temperatures of the [aP₄₄₄₃][AA]. For example for [AA]⁻ anion like [Cys]⁻ (202 °C), [Tyr]⁻ (231 °C), [Thr]⁻ (245 °C) and [Ser]⁻ (254 °C) are functionalised by SH or OH moieties have lower thermal decomposition temperature. For [AA]⁻ structures with ring in their side-chains and low negative charge densities, for example [His], [Phe], [Pro] and [Trp] have high T_d values with 300, 282, 280 and 277 °C respectively. For anion [Val], [Lys], [Ile],

[Leu], [Ala] and [Gly] all T_d are above 280 °C because the anions have only alkyl side chains which also results in a low negative charge density [71].

Goodrich *et al.* (2011), found that cation [P₆₆₆₁₄] is a very stable with a decomposition temperature as high as 420 °C when paired with stable anion [60]. This might be because of asymmetry of the [P₆₆₆₁₄] cation which increases in stability compared to smaller cation, [P₄₄₄₄]. By studying the decomposition temperature with various anions, it was found that the decomposition temperature decrease in order of [Tau] > [Gln] > [Pro] > [Met] > [Lys] > [Thr] > [Asn]. For glass transition temperature, the T_g for [P₆₆₆₁₄]⁺, varied from -86 to -69 °C lower than the values for the same anions with [emim], [P₄₄₄₄], [aP₄₄₄₃] cations [96].

Thermal properties for dicationic ILs (DILs) showed the T_g increase with alkyl side-chain length of the amino acid when DILs had the same dications, due to the van der Waals force between alkyl side chains. In DILs with the same alkyl link chain length, the T_g of DIL with asymmetric structure was nearly 6 °C lower than symmetric structure. For T_d , the alkyl side chain length of amino acids and the alkyl link-chain length of the dication also had a great influence on thermal stability. For example, DILs [Bis(mim)C₄]²⁺ was 40 °C higher than [bis(mim)C₂]²⁺ with same anions. This shows that increase of alkyl chain length of dication could enhance T_d [97].

In PILs, thermal stability showed that T_d of PILs on [TFMS], [PTS], [BF₄] and [Tf₂N] as anions were higher than chloride as anion which indicates that increased thermal stability. However, PILs with [Ac], [TFAc], [MS], [HFB], [Bz] and [NO₃] anions, the thermal stability decreased. This indicates that anion plays a key role in determining thermal stability. In T_g , the T_g for poly[DADMA][Cl] was found to be at 204 °C. By using inorganic anion, poly[DADMA][NO₃], the T_g reduced slightly to 197 °C. For PILs with organic anion, the T_g was reduced to 90-117 °C. This lowering in T_g , by a particular anion attributed to the larger size of the anion in PILs. The increased anion size may not render as efficient chain packing as [Cl] as anion of smaller size. This lead to lowering the of interchain interactions in the formed PIL than poly[DADMA][Cl]. This resulted in lowering the T_g temperature [74]. This is agreed by Tang *et al.* [82] that anions in PILs such as [BF₄] have a strong plasticizing effects thus improve flexibility of polymer chains, facilitate the segmental motion and reduce T_g of the PILs.

For PILs imidazolium based, the initial decomposition temperatures of PILs were up to nearly 300 °C under N₂ atmosphere. For glass transition temperature, the DSC curves of PILs with different anions showed that PILs- PF₆ and PILs-BF₄ were 68 °C and 135 °C respectively with no melting endotherm observed in DSC traces [76].

2.2 Review on CO₂ Sorption

The most common technology for CO₂ absorption in industry is using alkanolamine such as primary monoethanolamine (MEA), diethanolamine (DEA) and methyldiethanolamine (MDEA). These amines have been constantly synthesized to ascertain their capability in CO₂ capture. It can capture CO₂ up to 0.5 mol/mol. However, this caused a serious several drawbacks such as high volatility, corrosive in nature and higher cost for regeneration. Therefore, alternative to replace the usage of alkanolamine is highly needed. ILs has been proposed as a good replacement for alkanolamine since it is low volatility, low vapor pressure and high solubility with CO₂. This efficiency of CO₂ sorption by using ILs can be enhanced by tethering the amine group either cation or anion. The interaction between this amine and CO₂ would increase the CO₂ sorption capacity due to the chemical absorption. It has been reported that by tethering the amine on anion, the CO₂ sorption capacity can be as high as 1.0 mol/mol due to the formation of carbamic acid. However, the higher viscosity in ILs may attribute to the low efficiency and slow absorption kinetic thus difficult to apply in industry. Therefore by polymerized the ILs resulted in solid form with amine functionalized as anion seems promising for capturing CO₂ in natural gas.

2.2.1 CO₂ sorption on alkanolamine

Specifically, the desired properties of the amine include fast kinetic, absorption-desorption rate, absorption capacity and ability to reach 90% capture efficiency [101]. In recent times, polyamines have been discovered to have a very good CO₂ absorption capacity, high mass transfer and high reaction kinetics (mainly to the presence of multiple amine groups). It has been used as a promoter or activator in high absorption capacity solvents to enhance their CO₂ capture efficiency. The polyamines that contain primary or secondary amine group are usually used for enhancing amine-CO₂

kinetics whereas tertiary amino group will not be used as rate promoters due to their slow CO₂ absorption pathway [102].

Many studies have been devoted to improve CO₂ absorption and selectivity by chemical modification on the surface of solid materials possessing high surface area. The basic organic group (amine) and inorganic metal oxide (alkali metal or alkali-earth metal) are of particular interest. Amine-based adsorbents have widely been studied and exhibited the advantage as low heat of regeneration over aqueous amines due to the low heat capacity of solid supports. Their low CO₂ adsorption capacity and high cost, however, are the major challenges to commercialize [103].

Yang *et al.* (2015), have studied the use of perfluorinated silica-stabilized with dry alkanolamines (DA_f) for CO₂ capture. DA_f display high operational CO₂ capture efficiency with 98 wt% as compared to bulk MEA with only 60 wt%. This lower absorption of bulk MEA is due to mass transport arising from the large increase of viscosity due to carbamate salt formation. DA_f also exhibit extraordinary recyclability with a negligible decrease in absorption capacity over at least ten absorption-regeneration cycles. Moreover, the amine component of the DA_f is also isolated by the silica particles from pipelines and other corrosion sensitive materials [104].

Kim *et al.* (2013) have studied the CO₂ absorption by aqueous alkanolamines solution with different structures which is MEA 30wt%, DEA 30 wt%, TEA 30wt% and AMP 30 wt%. All the experimental absorbents showed higher CO₂ loadings with lower reaction temperature. While a primary amine, MEA, and a secondary amine, DEA, showed CO₂ loading limited to 0.6 (mol CO₂/mol amine), a sterically hindered amine, AMP showed higher CO₂ loading with 0.8 (mol CO₂/mol amine). This is because, AMP formed unstable carbamate and hydrolysis easily occurred, leading to the formation of free amines and bicarbonate ions. Therefore, AMP had higher CO₂ loadings compared to those for unhindered primary and secondary amines. However, the slopes of the graphs of MEA and DEA rapidly increased at CO₂ loadings higher than a certain value, whereas TEA and AMP yielded curves with gentle slopes. These results show that the carbamate reactions, which major reactions of primary and secondary amines, occur quickly, while the unstable carbamate reactions and

subsequent bicarbonate formation that appear in tertiary and sterically hindered amines occur slowly [15].

However, there are drawbacks linked with amines such as high vapour pressure, corrosive in nature and requires high energy input for regeneration. The high vapour pressure allows emission of amine gases into the air upon heating. The amines itself are also corrosive especially MEA which corrodes the equipment. The regeneration process leads to high energy consumption in order to break the chemical bonds formed between the CO₂ and amine [22]. However, the major drawback which limits the potential in using MEA in the capture process is the high energy for regeneration of MEA which could be as high as 3.3-4.4 GJ/ton CO₂. It has been reported that the amount of regeneration energy could account for 70-80 % of the entire operating cost of CO₂ capture plant [101].

2.2.2 CO₂ sorption on room temperature ionic liquids (RTILs)

ILs are promising candidates as absorbents for CO₂ removal because of their high thermal stability, negligible vapor pressure and tunable physicochemical properties [105]. Many research groups have carried out research on solubility of CO₂ in ILs [52, 53, 97, 106, 107]. Brennecke *et al.* (2003), were the first to report on CO₂ solubility. They reported that ILs with fluoroalkyl improves CO₂ solubility compared to non-fluorinated ILs [59, 62-64]. The anion plays a key role in determining CO₂ solubility in ILs and through physical adsorption with CO₂, less energy is needed for the regeneration of ILs [59]. The enthalpy required is less than 20 kJ/mol to release the physically adsorbed CO₂ in regeneration step, which is only a quarter of the energy consumed in amine-based method [65].

There were a number of factors that controlled the CO₂ solubility in the ILs which both cation and anion are related. The anion played the biggest role in CO₂ solubility. Anions that contain fluoroalkyl groups were found to have some of the highest CO₂ solubilities. As the number of fluoroalkyl groups increased, the CO₂ solubility also increased. For the cations, there are two factors that influenced the CO₂ solubility. The biggest effect was seen in increasing of alkyl chain length on the cation. For a given cation, the CO₂ solubility increased with increasing alkyl chain length [52, 108]. This might be due to entropic reasons that by increasing alkyl chain length, the

density of ILs decreases. Therefore, there are more free volume within the longer chain ILs [59].

Table 2.1: Absorption capacity of CO₂ by mixture of imidazole-based ILs [109]

Ionic liquids	Exp value (mol/mol)
[bmim][BF ₄]	0.0212
[bmim][BF ₄] + [NH ₂ -emim][BF ₄]	0.0698
[bmim][Tf ₂ N]	0.0378
[bmim][Tf ₂ N] + [NH ₂ -emim][BF ₄]	0.0747
[bmim][CH ₃ CO ₂]	0.0316
[bmim][CH ₃ CO ₂] + [NH ₂ -emim][BF ₄]	0.0291
[NH ₂ -emim][BF ₄]	0.0610

Mei *et al.* (2012), have studied the CO₂ sorption performance by imidazole based ILs mixtures [110]. It was showed that better CO₂ absorption capacity obtained for the mixtures of [bmim][BF₄] or [bmim][Tf₂N] with [NH₂-emim][BF₄] than single IL. However, the CO₂ sorption reduced after [NH₂-emim][BF₄] was mixed with [bmim][CH₃CO₂]. The reason might be that two kinds on ionic liquids interacted each other. Table 2.1 shows the results of CO₂ sorption capacity for the mixture of ILs. The mixtures containing anion [Tf₂N] and [BF₄] shows better CO₂ sorption which might result from the fluorination [64]. The regeneration performance of the ILs mixtures also shows good result where 10 times of absorption/desorption cycles still shows the quality of mixture remained basically unchanged.

Blath *et al.* (2012), have studied the absorption ability of carbon dioxide in ILs with basic anion like acetate, privalate, lactate and benzoate and imidazolium as cation [111]. The ILs showed chemisorptions due to a formation of carboxylate at the imidazolium ring. This is confirmed by ¹³C NMR analysis where the peaks can be related with the carbon atoms of the imidazolium ring. For CO₂-treated [EMIM][OAc], two new peaks can be found at 154.44 ppm which represents the carbon atom from CO₂, which is bound to the C2 atom of the imidazolium ring by forming the carboxylate. The second peaks at 141.63 ppm and stands for the C2 atom itself, which is linked to the carboxylate group. The unbound C2 carbon atoms to carboxylate can be found at 138.15 ppm. This mechanism discussed in Figure 2.2. For

the anions, they found that acetate gave the best absorption. For benzoate anions, the steric hindrances due to the benzol ring can effects the deprotonation step in reaction mechanism. For privalate anion, the extra CH₃ groups can also alter the chemisorptions ability slightly. This can lead to higher Henry's law contants compared to [EMIM][OAc].

Figure 2.2: Proposed mechanism of [EMIM][OAc]

Yunus *et al.* (2012), have studied the solubility of CO₂ in pyridinium based ILs with several anions and different of alkyl chain length (butyl, octyl, decyl) [112]. The results showed that the CO₂ absorption increases as alkyl chain length increased. This is due to the behaviour of entropic rather than enthalpic reasons, where increasing the cation alkyl chain length will decrease the density of the ILs and subsequently increasing free volume in the ILs for the absorption of CO₂ gas by space filling mechanism. For fluorinated anion, the solubility of CO₂ increases in the order of [C₄py][Dca] < [C₄py][TfAc] < [C₄py][Tf₂N]. This trend follows the order of fluorination presents in the anion and also the molar mass of the ILs. It can be concluded that an increase in the length of fluroalkyl leads to an increase in CO₂ solubility.

Anthony *et al.* (2005), have studied the anion effect of gas solubilities in ILs [64]. The results showed that water and benzene were most soluble, followed by nitroux oxide and carbon dioxide, ethylene, ethane and oxygen. Carbon monoxide solubility was below the detection limit. This results showed that gases with large dipole moments (*e.g.* water) or quadrupole moments (*e.g.* CO₂ and N₂O), and those with chance for specific interactions (*e.g.* hydrogen bonding) have the highest solubilities in

ILs. Whereas, the solubility of nonpolar gases are correlate well with polarizability. However, carbon monoxide does not follow this trend, which indicated that these factors cannot fully describe behaviour of gases in ILs. For the anions, it can be seen that [Tf₂N] anion increases all gas solubilities compared to [BF₄] and [PF₆]. By changing the cation from imidazolium to quaternary ammonium or pyrrolidinium with [Tf₂N] as anions, it gave little difference in CO₂ and O₂ solubility.

Husson *et al.* (2010), have studied the effect of water on CO₂ sorption by [emim][Tf₂N] [113]. It is observed that the solubility decreases with the mole fraction concentration of water (0.28 mole fraction) from 2.63×10^{-2} for the pure ILs to 1.88×10^{-2} which the reduction approximately 30% on the CO₂ solubility. The viscosities of the mixtures of [emim][Tf₂N] with water (0.300 mole fraction, 303 K) resulted approximately 40 % lower than pure ILs. It concluded that the viscosity of the ILs medium can be significantly reduced while maintaining the same order of magnitude for the low pressure of CO₂ solubility. This is because the viscosities can considerable modifying the transport of the gas in liquid medium. Thus it can substantially affect the characteristics of the ILs medium as an absorbent for carbon dioxide.

In the event of conventional ionic liquids, carbon dioxide is absorbed by occupying free space between the ions, thus high pressure is needed in the physical adsorption process. However, the adsorption capacity is relatively low [21].

2.2.3 CO₂ sorption on task specific ionic liquids (TSILs)

Owing to the limitations in adsorption capacity seen for RTILs in physical adsorption mechanism, an attention now focused on a new concept where the advantages of ILs are combined with the incorporation of functional groups to allow chemical binding of CO₂ to the absorbents. They are some functional groups that can enhance the CO₂ sorption capacity such as carboxylate functionality, amine functionality and combined functionality. The CO₂ should bind to the functional group in a thermodynamic sense and the kinetics should be sufficient enough for this process to operate at a fast enough absorption rates. Therefore, the absorption step must not be too exothermic so the removal of CO₂ in regeneration step can be conducted without high energy requirements. This is because, by using conventional amines like MEA, DEA or MDEA have high relatively large exothermic sorption enthalpies (above -80 kJ/mol).

Thus, by functionalize ILs exhibiting less exothermic sorption enthalpy would be very attractive [21].

The remarkable properties of ILs for CO₂ sorption are mostly decided by cations, anions and factors associated with structural modification of duo. As reported, anion plays the biggest role in CO₂ sorption which anions with fluoroalkyl groups were found to have the highest CO₂ solubility. By increasing the quantity of fluoroalkyl groups, the CO₂ solubility also increased. Whereas in the case of cations, there were two factors that controlled the CO₂ solubility in ILs. First is when the alkyl chain length on the cation increased and the second factor was to attach a functional group like ether to cation. This is to create a greater free volume or by incorporating a CO₂-philic carbonyl functional moiety such as amine, alcohol, carboxylic and nitrile. This promising strategy leads to the synthesis of TSILs [65, 108].

Much higher absorption capacity can be achieved if the CO₂ is chemically absorbed instead of physically [66]. Bates *et al.* (2002), prepared ILs with ions incorporating amino- functional groups for this purpose, for example 1-(3-propylamino)-3-butylimidazolium-tetrafluoroborate, [apbm][BF₄], where the primary amine is covalently tethered at the cation [67]. This IL absorbed 0.5 mol CO₂ / mol IL at P(CO₂) = 1 atm and room temperature during 3 hour exposure period. Since then, a number of other researchers [60, 68, 70, 71, 96, 114, 115] have also studied CO₂ absorption in amine-functionalized cation and anion ILs. Some of the best performing materials are the di-amino functional protic ILs, which have absorption capacities >12 wt% [88, 116].

Sharma *et al.* (2012), have studied the series of ether functionalized on imidazolium cation based ILs, [C₂Omim][X] [117]. Among the functionalized ILs, ether functionalized have been paid much attraction due to their attractive physical and chemical properties which include air and moisture stability, selective, thermally stable, long life operational and a promising candidate for CO₂ capture. The results showed that ether functionalized shows significantly high absorption capacity for CO₂ which reached about 0.9 mol CO₂ per mol ILs at 1.6 bar, 303 K. The CO₂ absorption results shows that the absorption of CO₂ in ether functionalized is a chemical process which follows 1:1 mechanism and forms a carbamic acids. The detailed mechanism is presented in Figure 2.3.

Figure 2.3: Proposed mechanism of CO₂ absorption by ether functionalized ILs.

Figure 2.3 shows that the lone pair of electrons on oxygen atom of the ether group attacks as a nucleophile on the carbon atom of CO₂ and lead to formation of carboxylic acid. This indicates the predominance of 1:1 mechanism, where the CO₂ reacts with one mole ILs to form a carbamic acid. This interaction of CO₂ with ILs are shown on FTIR spectra where two new peaks appeared around 1700 cm⁻¹ and 1405 cm⁻¹ for (-C=O str) and (-O-H in plane bend) of the carboxylic acid. These peaks confirm the chemical process between ether functionalized and CO₂.

On 2012, Sharma *et al.* (2012), also reported that acid functionalized ILs, [Cmmim][X] for CO₂ sorption also reaches 0.9 mol CO₂ per mol at 1.6 bar, 303 K. The reason it is not achieved the maximum capacity maybe due to the high viscosity of ILs where the formation of hydrogen bonding network increases rapidly [108]. The mechanism indicates that the lone pair of electrons on oxygen atom of the acid group attack as a nucleophile on the carbon atom of CO₂ and lead to the formation of

anhydride. This type of mechanism also called 1:1 mechanism where 1 mole of CO₂ reacts with 1 mole of ILs. The detailed mechanism is presented in Figure 2.4.

Figure 2.4: Proposed mechanism of CO₂ absorption by acid functionalized ILs

Hu *et al.* (2014), have studied the CO₂ sorption with amino group ILs. The results showed that the more amine groups in ILs led to higher CO₂ sorption capacities [118]. The CO₂ results showed that [TETAH][BF₄] gave higher CO₂ sorption as high as 0.96 mol/mol than [EDTAH][BF₄] with 0.487 mol/mol and [MEA][BF₄] with only 0.246 mol/mol. This indicates that the greater number of an amine group in cation, the more CO₂ is absorbed. They also found out that factors such as temperature, gas flow rate and water content also had the most significant impact on the CO₂ sorption capacity. ILs [TETAH][BF₄] with 0% water gave 0.96 mol/mol. But when the water content of [TETAH][BF₄] reached 40%, CO₂ sorption capacity increased to 2.04 mol/mol. They suggested that reaction between CO₂ and H₂O, generate more H⁺, thus enhancing the absorption of CO₂. Therefore, it shows that with the addition of water, the CO₂ sorption capacity increases since the water also reduces the viscosities of ILs.

2.2.4 CO₂ sorption on amino acid ionic liquids (AAILs)

Amine functionalized-anion ILs have also been studied, mainly using amino acids as the anion [69-71]. Amino Acid Ionic Liquids (AAILs) were first prepared by

Fukumoto and Ohno [72] by using 1-ethyl-3-methylimidazolium as cation, ([emim]) with 20 different natural amino acids as anion [73].

Goodrich *et al.* (2011), suggested that 1:1 (CO₂: IL) mol ratio can be achieved when the amine is tethered to the anion instead of the cation [96]. The uptake of CO₂ by this chemical mechanism is described in Equations 2.1 and 2.2; since [AA]⁻ have structure of [H₂N-CHR-COO⁻], they are represented here as R⁻ NH₂.

Theoretical calculations showed that the dianion formed in the Equation 2.2 is chemically unstable therefore the reaction would expect to terminate at Equation 2.1 upon addition of CO₂ to AAILs. This indicates a potential absorption stoichiometry of 1:1 (CO₂: IL). However the exact mechanism is still under debate. At higher pressures, there is an increased uncertainty where there is increased capacity due to physical adsorption, but at low pressures, chemical absorption is dominant. Calculations showed that tethering the amine to the cation favored the formation of the carbamate, reflecting the electrostatic stability of the zwitterions product. However, by tethering the amine to the anion favored the carbamic acid, reflecting the instability of the product dianion. These trends are most pronounced when the charge center and amine are in close proximity [68].

Sistla *et al.* (2014), have reported that AAILs with butylmethylimidazolium, [bmim], as cation gave CO₂ absorption within the range 0.32 – 0.62 mole CO₂ per mole IL at 2 bar pressure and 298 K [70]. The result showed that [bmim] [Arg] has the highest CO₂ absorption with 0.62 mol CO₂ / mol IL followed by [bmim] [Lys] (0.48 mol /mol) and [bmim] [His] (0.45 mol/mol). This shows that AAILs with more than one amine site show higher CO₂ absorption capacity than AAILs with only one amine group tethered to the anion. This is also agreed by Saravanamurugan *et al.* (2014), that AAILs based on naturally amino acids *i.e.* lysine (Lys), histidine (Hist), asparagines (Asn), glutamine (Gln) that contain one amine group in addition to the amino-acid functionality [105]. An absorption capacity of 2.1 mol/mol was measured for [N₆₆₆₁₄][Lys]. This suggested that both amine groups in lysine, reacted completely

with CO₂ to form [N₆₆₆₁₄][Lys]-CO₂ as shown in Figure 2.5. The CO₂ absorption resulted in the formation of carbamic acids by reaction of CO₂ with amine groups by 2:1 mechanism.

Figure 2.5: The pathway for the formation of the [N₆₆₆₁₄][Lys]-CO₂ [105]

Gurkan *et al.* (2010), [68] and Goodrich *et al.* (2011) also studied the CO₂ absorption in AAILs by using trihexyltetradecyl phosphonium [P₆₆₆₁₄] as cation and methionine and proline as anions [96]. The results showed CO₂ absorption at 0.88 mol CO₂ / mol IL at 1 bar pressure. Therefore, they have shown that phosphonium-based AAILs can react with CO₂ in 1:1 stoichiometry.

Zhang *et al.* (2012), studied CO₂ capture with dual amino functionalized phosphonium ionic liquids (3-aminopropyl)tributylphosphonium amino acids, [aP₄₄₄₃][AA] [71]. The result showed that the absorption of CO₂ was less than 0.2 mol/mol after 2 hour exposure because of high viscosities. However, after immobilizing these ILs on porous SiO₂, the results showed that the absorption of CO₂ was close to 1:1 by mol in about 80 minutes. These AAILs often suffer the problem of having high viscosity and also have lower thermal stability than general ILs.

Xue *et al.* (2011), have synthesized dual amino ionic liquids, with amino-functionalized imidazolium cation and taurine as anion; [aemmim][tau] [119]. Taurine (Tau), had been chosen since it is cheap, easily obtained and naturally occurring amino acid with a better stability than most of other amino acids. They found that CO₂ absorption capacity reached 0.9 mol CO₂ / mol IL at ambient pressure and 303 K. Since there are two amines tethered to the anion and the cation in [aemmim][tau], so the maximum absorption capacity may reaches 1.5 mol CO₂ per mol of [aemmim][tau] as shown in Figure 2.6. The interactions of carbon dioxide and

[aemim][tau] shows that the absorption is chemical process. In FTIR, carbamate peak C=O appeared at 1661 cm^{-1} after absorption.

Figure 2.6: Proposed mechanism of [aemim][tau] with CO_2 [119]

Chen *et al.* (2013), have investigate the physical and chemical interactions between CO_2 and amine functionalized ILs which is [aEMMIM][BF_4] [120]. The results showed that there are both physical and chemical interactions between amine-functionalized ILs and CO_2 . They observed that 21% of [aEMMIM][BF_4] interacted with CO_2 chemically at 1:1 (CO_2/IL) which lead to 94% contribution to the solubility. Whereas 79% of [aEMMIM][BF_4] interacted physically leading to 6% contribution. The CO_2 sorption process by [aEMMIM][BF_4] are shown in Figure 2.7. The high viscosity of [aEMMIM][BF_4] resulted the difficult diffusion of CO_2 through [aEMMIM][BF_4] which prevents it from interacting chemically with CO_2 .

Figure 2.7: Proposed CO_2 absorption process by [aEMMIM][BF_4] [120]

Feng *et al.* (2010), have studied the absorption of CO₂ in aqueous solution of functionalized ionic liquids with MDEA [17]. They used lysine and glycine as anion and ammonium based as cation with different of alkyl chain length. It had been found that adding amino acid as anion greatly reinforced the CO₂ absorption of MDEA aqueous solution. The results showed that by using 15% AAILs + 15% MDEA had higher absorption rate and larger uptake capacity than total 30% amines. Table 2.2 shows the absorption capacity of aqueous solutions of 15% AAILs + 15% MDEA. Table 2.2 shows that the lysine based ILs was much higher than glycine based ILs which results from the two amine groups in one lysine molecule.

Table 2.2: Absorption capacity of aqueous solutions of 15% ILs + 15% MDEA

Absorbent	Mol CO ₂ / mol amines
15% [N ₁₁₁₁][Gly] + 15% MDEA	0.562
15% [N ₂₂₂₂][Gly] + 15% MDEA	0.643
15% [N ₁₁₁₁][Lys] + 15% MDEA	0.694
15% [N ₂₂₂₂][Lys] + 15% MDEA	0.740
15% MEA + 15% MDEA	0.363

Zhang *et al.* (2013), have studied the absorption of CO₂ by amino acid-functionalized and traditional dicationic ionic liquids, (DILs) [97]. The results showed that CO₂ absorption capacities of pure AA-DILs were enhanced compared to monocationic ILs to give a carbamate precipitate at ambient pressure and 40 °C. They also studied the effect by addition of water to DILs which it might give an efficient manner for CO₂ gas capture through mixing these DILs with water. The results showed that by adding at least 60% water in [bis(mim)C₄][Pro]₂, the viscosity decreased hence the performance of CO₂ gas capture was enhanced largely.

Goodrich *et al.* (2011), studied the CO₂ sorption on amine functionalized anion-ILs [60]. The cation used was phosphonium based, [P₆₆₆₁₄], and amino acids as anion. The result showed that all AAILs synthesized rise above 0.5 mol/mol indicates the 1:1 mechanism was dominant. For [P₆₆₆₁₄][Lys] rises above 1 mol/mol, but in [Lys], there are two amines so its theoretical limit for the 1:1 absorption mechanism is 2 mol/mol. They also studied the effect of water on AAILs for CO₂ sorption. For [P₆₆₆₁₄][Pro]

with 4 wt% of water, capacity of CO₂ sorption appears to be slightly decreased at lower pressures but at higher pressures it become equivalent. However, when large amount of water quantities are present, it can be seen that the water seems to have substantial impact on CO₂ sorption capabilities of ILs. They tested when 14 wt% of water are present on [P₆₆₆₁₄][Met], the CO₂ capacity reduced by approximately 0.2 mol/mol at 0.25 bar and by 0.1 mol/mol at 1 bar.

A hydrophilic AAILs, [C₂OHmim][Gly] has been synthesized to enhance the process of MEA for CO₂ capture [61]. They studied the CO₂ capture into different mole ratios of MEA/[C₂OHmim][Gly]. The results showed that the capacity of MEA solution was 0.430 mol/mol and for [C₂OHmim][Gly] was higher at 0.545 mol/mol. By increasing the amount of [C₂OHmim][Gly], the CO₂ absorption also increased. When the mole ratio of MEA and [C₂OHmim][Gly] was 7:3, the capacity of mixed solution was 0.534 mol CO₂/mol absorbent was almost the same as pure [C₂OHmim][Gly]. Therefore, further increase of [C₂OHmim][Gly] seems no significant enhancement on the CO₂ capture. The results indicated that the interaction of MEA/[C₂OHmim][Gly] on CO₂ absorption involved a mutual promoting relationship that enhanced the absorption capacity. As reported in most research, [69, 121], In the system for MEA solution, (MEA denoted as RR'NH) reacts with CO₂ through the formation of zwitterion as intermediate:

Then the zwitterions undergo the deprotonation by a base B (base catalyst), where B is a base that could be an amine, OH⁻, or H₂O. Thereby, these results in the formation of carbamate:

Meanwhile the hydrophilic AAILs, [C₂OHmim][Gly], also reacts with CO₂ which the reaction is similar to that between MEA and CO₂. In the system of AAILs, the base B is mostly [C₂OHmim][Gly]. Therefore, in the system of MEA/[C₂OHmim][Gly] solution, both of the two components could react with CO₂ and they would compete each other.

To study the effect of water in ILs, McDonald *et al.* (2014), reported that CO₂ capture by AAILs are largely impacted with the presence of water [91]. The amino acid as anions plays only a transitory role in the CO₂ capture in the first minutes of exposure to wet CO₂ stream. The carbamate formed by the amine-functionalized in

amino acids reacts with CO₂. This carbamate releases the covalently bounded with CO₂ thus forming mixture of carbonate and bicarbonate.

Munoz *et al.* (2009), have come out with the mechanism when AAILs react with CO₂ [122]. The combination of CO₂ with the absorbents gives rise to a carbamate as shown in Figure 2.8. In Figure 2.8 shows that when amino acids dissolved in water, exist as a zwitterionic form (II-A) which means, that the amino group is protonated and hence not able to react with CO₂. Therefore, equimolecular amount of base was added to free the amino group in aqueous solution (III-A). This amino interacts with CO₂ to form a complex (IV-A) by an equilibrium reaction. Then, a basic group is needed to remove a proton to give the final carbamate (V-A). It should be noted that not only amino groups can react with CO₂, but other groups that present in the system are also capable.

Figure 2.8: The formation of carbamate

If the pH of solution is higher than 7, hydroxide ions react with CO₂ to give hydrogen carbonate ions as shown in Equation 2.3 which can react again with hydroxide ions (Equation 2.4). Thus two hydroxide ions react very fast with one CO₂ molecule to give a system where only carbonate ions are theoretically present at the

end of the process. On the other hand, carbonate ions react with CO₂ molecules (Equation 2.5) to give hydrogen carbonate species.

Thus, in the first absorption, CO₂ is transformed into carbamate as shown in Figure 2.8 and into carbonate and hydrogen carbonate ions. After the first desorption, the carbamate formation is reversed but some of the carbonate and hydrogen carbonate ions remain in the system and therefore, the CO₂ removal is not completely achieved in desorption process. Hence, in second absorption, the CO₂ can only become a carbamate thus indicates lower absorption [122].

Table 2.3 shows a literature data on CO₂ sorption in AAILs. The result shows that most of the AAILs absorb CO₂ at low pressure (1 to 2 bar) and ambient temperature (298 K to 313 K). The results showed that AAILs able to capture CO₂ up to 1 mol/mol thus indicates that mechanism 1:1 between AAILs and CO₂ is achieved. This value is higher than alkanolamine which limited only 0.5 mol/mol. By using amine functionalized anion, AAILs, able to absorb CO₂ higher than RTILs since chemical absorption is involved in AAILs rather than physical adsorption in RTILs. However, by tethering amine either cation or anion, it will create a liquid with high viscosity thus it is difficult to handle.

Table 2.3: Literature data for CO₂ sorption by AAILs.

2.2.5 CO₂ sorption on polymerized ionic liquids (PILs)

In CO₂ separations, ILs have been proposed as alternatives for CO₂ capture media since it is in solid form thus easier to handle. Tang *et al.* (2005), is the first group who reported on PILs for CO₂ sorption. They found out that polymers from ILs monomers had higher CO₂ sorption capacity than RTILs [80]. PILs were shown to exhibit several times higher than their monomeric forms or commonly used ILs. In PILs, they have much faster CO₂ sorption and desorption rates than others RTILs [74].

Since then, PILs have recently attracted attention for CO₂ absorption [40, 74-78]. This is due to larger free volume in PILs which can trap a larger amount of CO₂. The properties of PILs also can be customized by varying the combination of polycation-anion pair [79]. The capacity of CO₂ capture depends on the type of polycation, polymer backbone, anion and substituents [80]. The polycation type is considered a decisive factor in CO₂ capture performance, ammonium-based PILs having capacity than imidazolium-based PILs [80, 81]. By comparing the backbone of cation, PILs with a polystyrene backbone, vinylbenzyltrimethylammonium ([VBTMA]), gave higher CO₂ sorption than those with a polymethylmethacrylate, ([MATMA]) backbone. This is because the structures with polystyrene backbone in cation exhibit higher adsorption capacity and the larger substituent on imidazolium cation pose hindrance and lower the adsorption. [81].

The result showed that poly[VBTMA][BF₄] had a higher CO₂ sorption capacity than poly[MATMA][BF₄] [82]. This is probably because of polystyrene backbone was more rigid than [MATMA]. They also studied on the effects of alkyl chain length and observed that with long alkyl chain, it may reduced the CO₂ sorption due to steric effects in cation may hinder the interaction. The anions in PILs also played an important factor. The results showed that poly[VBTMA][BF₄] had strong interaction with CO₂ hence gave higher CO₂ sorption capacity. However, with [PF₆] and [Tf₂N]

anion, CO₂ sorption capacity decreased slightly and showed a very low CO₂ sorption capacity. This contrasts to the RTILs that in PILs, fluorine atom not a decisive factors in determining CO₂ sorption.

Tang *et al.* (2005), also reported that PILs able to adsorb CO₂ even at low pressure [81]. The results showed that poly[VBtMA][BF₄] and poly[MATMA][BF₄] took up 0.102 and 0.079 mol/mol respectively at 0.78 bar pressure and 298 K. Their monomers showed no measureable sorption of CO₂ because of crystalline structures in low pressure. In PILs, it took only several minutes to reach 90% capacity and less than 60 minutes for equilibrium. The specific surface area for poly[VBtMA][BF₄] was 0.46 m²/g and 20.5 m²/g for poly[MATMA][BF₄]. This is due to a non porous structures in poly[VBtMA][BF₄] thus gave lower specific surface area while poly[MATMA][BF₄] was porous due to the uneven structure thus gave a larger surface area. Therefore, they proposed that the CO₂ sorption in PILs involves absorption (the bulk) and adsorption (the surface).

The rates of adsorption and desorption of PILs is fast as compared to RTILs. This might be because of the bulk adsorption phenomenon appears to govern the capture progress. RTILs with polymerizable entities show higher permeability, solubility and diffusivity values for CO₂, N₂ and CH₄. These PILs structures can capture almost double the amount of CO₂ compared to the RTILs. However, with longer alkyl chains on PILs cation, may pose a steric hindrance between CO₂-cation interaction. This may shrink the microvoid volume which resulting from plasticization and rigidity due to crosslinking, thus decreasing the CO₂ sorption capacity [125].

CO₂ sorption of the PILs was much faster than RTILs. It took only 4 min for Poly[VBIT] and Poly[VBIH] and 3 min for Poly[BIMT] to reach their 90% sorption capacities and about 30 min to reach their full capacities. In contrast, it took more than 400 min for the monomers, BIMT and [bmim][BF₄] to reach their equilibrium [80]. The fast of adsorption and desorption rates in PILs might be because of polymers are solids at room temperature. The calculated of CO₂ adsorption assuming a monolayer of polymer particles surface showed only 4% of the measured total of CO₂ sorption capacities. This indicates that the bulk of polymer particles played a major role in CO₂ sorption. Therefore, CO₂ adsorption involves more on adsorption in the bulk but less adsorption in the surface [80].

Yu *et al.* (2013), have prepared a new porous polymeric particles, *i.e.* poly[VBTEA][Cl], poly[VBTEA][BF₄] and poly[VBTEA][PF₆] which prepared from crosslinking polymerization of 4-vinylbenzyltriethylammonium with *N,N*-methylenebisacrylamide *via* inverse suspension polymerization [78]. To get polymer microparticles with porous structure and larger special surface area, PEG 600 used as porogen since it can be conveniently removed to form pores. The apparent porosities are estimated to be 55 %, 69.7 % and 64.3 % respectively. The porous polymeric microparticles exhibited high CO₂ sorption capacity of poly[VBTEA][PF₆] with 14.04 mg/g, poly[VBTEA][BF₄] with 11.84 mg/g and poly[VBTEA][Cl] with 10.40 mg/g.

Privalova *et al.* (2013), reported that poly[BiEMA][PF₆] showed higher CO₂ sorption at 0.029 mol/mol followed with poly[BiEMA][BF₄] with 0.022 mol/mol [79]. Contrary to RTILs, the presence of F atoms in PILs seems to be not a decisive factor to enhance CO₂ sorption. Poly[BiEMA][OTf⁻] and poly[BiEMA][NTf₂⁻] showed only 0.019 and 0.018 mol/mol respectively. This is due to the bulky anions in [OTf⁻] [NTf₂⁻] may decrease the spare volume thus prevent the CO₂ penetration towards polycation.

Wilke *et al.* (2012), have study to enhance the CO₂ sorption by mesoporous PILs via a hard templating of silica nanoparticles [126]. They studied whether the presence of pronounced specific surface area can increase the capacity CO₂ uptake even more. It was found that the highest uptake for mesoporous PILs (mpPIL) is 0.46 mmol/g, higher than PILs with 0.13 mmol/g and the monomeric species only 0.02 mmol/g at 273 K, 1 bar pressure. PILs have known as powerful CO₂ adsorbents and usually it is found that PILs shows a higher CO₂ uptake compared to the monomer analogues. The mesoporous PILs showed a significantly faster CO₂ adsorption than nonporous PILs. It also showed that the adsorption into the bulk PIL is much slower at 30 h, than mesostructured PILs only takes 5 min. Hence, the beneficial effect of the additional specific surface area was proven while maintaining and increasing the favourable interactions of the ILs with CO₂. The presence of large mesopores can significantly boost the mass transfer through the system which is beneficial for many applications.

Bhavsar *et al.* (2012), studied the effect of anion on CO₂ sorption. The cation used was poly[DADMA] and the anion used was a different types of counter ions such as organic anion; carboxylates (Ac, TFAc, HFB, Bz), sulfonates (MS, TFMS, PTS) and inorganic anions (BF₄, NO₃, Cl) [74]. The CO₂ sorption coefficient (S_{CO2}) on various

carboxylate based PILs was increased on order of [TFAc] < [HFB] < [Bz] < [Ac] by following the order of increasing their basicity (PKa of conjugate acid: [TFAc]=0.0 < [HFB]=0.4 < [Bz]=4.2 < [Ac]=4.8. This behaviour of PILs is similar to ILs where by increasing basicity of anion, the CO₂ sorption also increased. However, for sulfonated anions, S_{CO2} followed the order of [TFMS] > [PTS] ≈ [MS] where pKa of conjugate acids for [TFMS]=-13, [PTS]=-2.8 and [MS]=-2.0. Thus basicity of the anion may not solely responsible for increasing the CO₂ sorption in PILs. Besides basicity, fractional free volume (FFV) in polymer matrix may also compete for governing the CO₂ sorption. For PILs containing inorganic anion (Cl, NO₃ and BF₄), The results also showed that S_{CO2} and selectivities for S_{CO2}/S_{H2} and S_{CO2}/S_{N2}, increased with increasing molar mass of the anion. However, this parameter of molar mass was not applicable in case of PILs with carboxylated and sulfonated anions.

Xiong *et al.* (2012), studied PILs which prepared by melt condensation polymerization with stannous octoate as catalyst. The results showed that the CO₂ sorption capacities for PILs are higher than in ILs [76]. For Poly[EEIm][PF₆] and poly[EEIm][BF₄] took up 0.042 and 0.045 mol/mol higher than the monomer with only 0.021 and 0.01 mol/mol respectively. However in the case of [HHIm] [PF₆] provided the highest CO₂ sorption capacity with 0.1 mol/mol. In particular, PF₆-improved the CO₂ solubility in ILs and PILs. These results suggested that the association of CO₂ with the anion was the best indicator of CO₂ solubility in imidazolium-based ILs. It can be seen that the [HHIm][PF₆] presented the highest CO₂ solubility among all the ILs and PILs. This may be due to the association of CO₂ with the anion and the hydrogen bonding interactions between the hydroxyl groups of [HHIm][PF₆] and CO₂ [76].

Sorption rate for these PILs is really fast compared to RTILs. It took several minutes for them to reach 95%, to their equilibrium where as for RTILs, [MABI][BF₄] and [bmim][BF₄] took 400 min to reach equilibrium. The fast sorption of PILs is affected neither by particle size nor by surface area. When replacing the [BF₄] in poly[VBBi][BF₄] with [Cl] anion, poly[VBBi][Cl] showed slower sorption rate even with the same magnitude of particle size suggesting that the fast CO₂ sorption is characteristic of PILs [80, 82].

The isothermal process of CO₂ sorption in PILs was found to be well fitting into dual-mode sorption model which describe the gas solubility in glassy polymer. This

suggests that the CO₂ sorption into PILs had two parts. One dissolved into matrix and the second adsorbed into microvoids following Langmuir hole-filling process. With the same backbone and similar anion, the CO₂ sorption is found to decrease in order of ammonium > pyridinium > phosphonium > imidazolium cations. By comparing the computed values of Henry's law constant (k_D) and the affinity constant for Langmuir mode, it is found to be in same order of magnitude. This is showed that the ammonium cation has the strongest interaction with CO₂ whereas the imidazolium has the weakest. Ammonium based PILs has a high saturation capacity C_H for Langmuir mode, suggesting a high fraction of microvoids compared to imidazolium-based ones [82].

Table 2.4: Literature data for CO₂ sorption in PILs

PILs	P (bar), T (K)	Mol /mol	Ref
Poly[VBtMA][PF ₆]	0.789 bar, 295 K	0.11	[81]
Poly[VBtMA][Tf ₂ N]	0.789 bar, 295 K	0.029	[81]

Poly[MATMA][BF ₄]	0.789 bar, 295 K	0.080	[81]
Poly[VBtMA][BF ₄]	0.789 bar, 295 K	0.102	[81]
Poly[VBTEA][BF ₄]	0.789 bar, 295 K	0.049	[81]
Poly[VBtBA][BF ₄]	0.789 bar, 295 K	0.031	[81]
Poly[VBIH][BF ₄]	0.789 bar, 295 K	0.028	[80]
Poly[VBIT][BF ₄]	0.789 bar, 295 K	0.022	[80]
Poly[BiEMA][BF ₄]	1 bar, 298 K	0.022	[79]
Poly[BiEMA][PF ₆]	1 bar, 298 K	0.029	[79]
Poly[BiEMA][OTf]	1 bar, 298 K	0.019	[79]
Poly[EEIm][PF ₆]	1 bar, 298 K	0.042	[76]
poly[EEIm][BF ₄]	1 bar, 298 K	0.045	[76]

Table 2.4 shows a literature data on CO₂ sorption on PILs reported. It can be seen that all PILs have low CO₂ sorption capacities (average 0.05 mol/mol) at low pressure (up to 1 bar). This is due to low physical adsorption capacities occurred in most PILs as compared to AAILs. Therefore, by tethering the amine functional in PILs may enhance the CO₂ sorption capacities and would overcome the viscosity problem in ILs.

CHAPTER 3

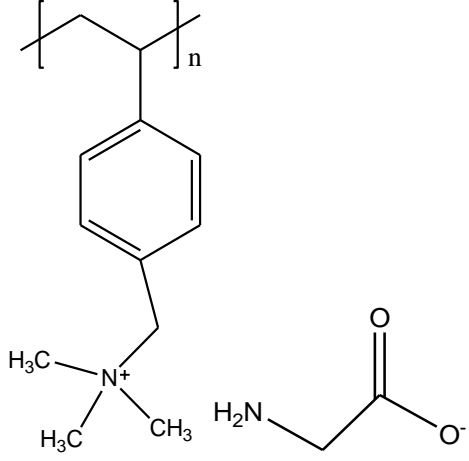

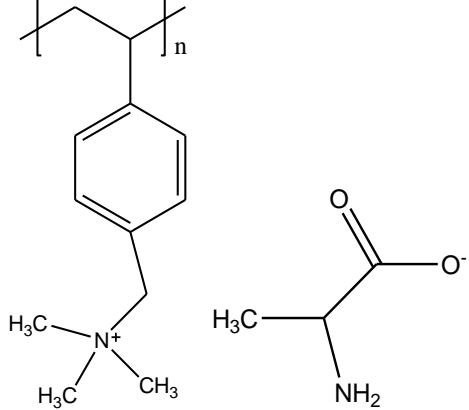

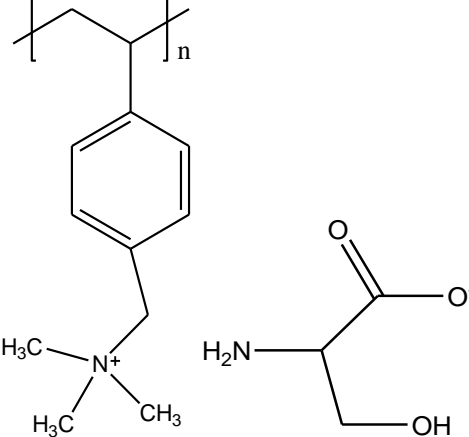

RESEARCH METHODOLOGY

It is important to understand the major factors that affect the CO₂ solubility in ILs and to produce ILs that has high potential for CO₂ sorption. ILs that contains functional group either in cation or anion or both may enhance the CO₂ sorption in ILs.

In this study, twelve amino acid polymerized ionic liquids (AAPILs) have been synthesized where the monomers are amino acids ionic liquids (AAILs) which will be polymerized by using radical initiator AIBN. Amino acids were used as anion with amine functional groups in their amino acids structure. By tethering the amine groups in anion, it can enhance the CO₂ sorption by following the mechanism of 1:1 as suggested by Goodrich *et al.* (2011) [96]. The anions are glycine [Gly], alanine [Ala], serine [Ser], proline [Pro], taurine [Tau], histidine [Hist], lysine [Lys] and arginine [Arg].

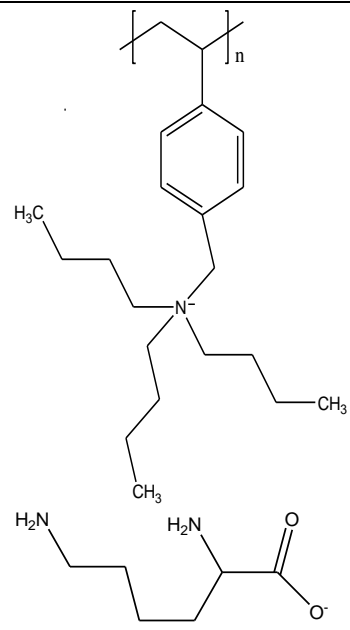

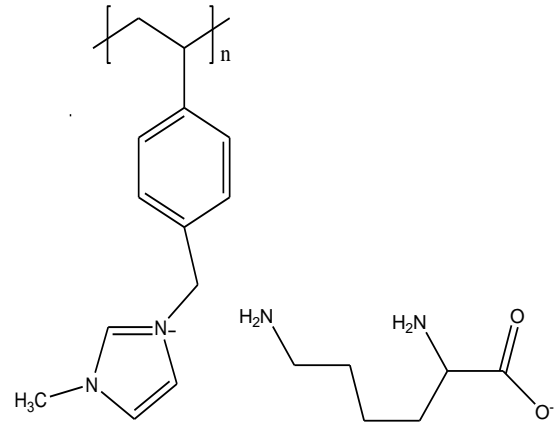

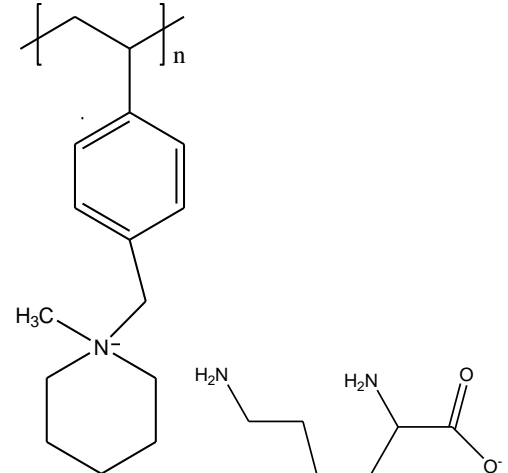

These anions have been chosed to study the amine functionality for reaction with CO₂ as amino acid [Gly], [Ala], [Ser], [Pro] and [Tau] contain one functional amine and for [Hist], [Lys] and [Arg] contain several additional amines which expected to give higher CO₂ uptake. In addition, these types of amino acids are usually used for CO₂ sorption as reported in literature. The cations are vinylbenzyltrimethylammonium [VBTMA], vinylbenzyltriethylammonium [VBTEA], vinylbenzyltributylammonium [VBTBA], vinylbenzylmethylimidazolium [VBMI] and vinylbenzylmethylpiperidinium [VBPPN]. The structures for all the AAPILs synthesized are structured in Table 3.1.

Table 3.1: Polymer name and monomer structure

3.1 Materials

The chemicals used in the synthesis of AAPILs were (vinylbenzyl)trimethylammonium chloride 99%, 4-vinylbenzyl chloride, 2,6-di-tert-butyl-4-methylphenol (DBMP) 99.0%, glycine, L-alanine, L-serine, L-proline, L-histidine, lysine, L-arginine and anion exchange resin used was Amberlyst A-26 (hydroxide, OH⁻ form) which was purchased from Sigma Aldrich, Malaysia. 1-methylimidazole, 1-methylpiperidine, triethylamine 99.5%, tributylamine 99.5%, taurine, methanol, ethanol, diethylether, ethyl acetate and acetonitrile are purchased from Merck, Malaysia. Radical initiator used was α, α' -Azobisisobutyronitrile (AIBN) was purchased from R&M, Malaysia. All chemicals used in synthesis and purification are used without any further purifications. Purified gases were supplied by Linde Gases Sdn. Bhd Malaysia were used for the CO₂ measurement. The grades of gases used are carbon dioxide (CO₂) with purity 99.9%, methane (CH₄) with purity 99.99% and nitrogen (N₂) with purity 99.9%.

3.2 Synthesis of Ionic Liquids, RTILs

3.2.1 Synthesis of (vinylbenzyl)tritethylammonium chloride, [VBTEA][Cl]

4-vinylbenzyl chloride (79.36 g, 0.52 mol), triethylamine (50.59 g, 0.5 mol) and 0.4 g of DBMP were added in dried 250 ml three necked flask. The reaction mixture is stirred under nitrogen at 50 °C for two days. The white solid formed [VBTEA][Cl] is washed with diethylether and filtered and further dried under vacuum at 60 °C for 2 days. The synthesis route is shown in Figure 3.1.

Figure 3.1: Synthesis route of [VBTEA][Cl]

3.2.2 Synthesis of (vinylbenzyl)tributylammonium chloride, [VBTBA][Cl]

Similar procedure used as describe in 3.2.1 to synthesized [VBTBA][Cl] by replacing triethylamine with tributylamine. The white solid formed is washed with diethylether, filtered and dried in vacuum oven at 60 °C for 2 days.

3.2.3 Synthesis of (vinylbenzyl)methylimidazolium chloride, [VBMI][Cl]

4-vinylbenzyl chloride (79.36 g, 0.52 mol), 1-methylimidazole (41.05 g, 0.5 mol), methanol and 0.4 g of DBMP were added in dried 250 ml three necked flask. The reaction mixture is stirred under nitrogen at 50 °C for two days. The yellow color viscous liquid is washed with diethylether and ethyl acetate. Two layers are formed. The upper layer was decanted and this was repeated for 3 times to remove any excess reactant. The solvents are removed by using rotary evaporator at 50 °C with reduced pressure. It was further dried by using vacuum oven for 2 days. The synthesis route is shown in Figure 3.2.

Figure 3.2: Synthesis route for [VBMI][Cl]

3.2.4 Synthesis of (vinylbenzyl)methylpiperidinium chloride, [VBPPN][Cl]

4-vinylbenzyl chloride (79.36 g, 0.52 mol), 1-methylpiperidine (49.59 g, 0.5 mol), methanol and 0.4 g of DBMP were added in dried 250 ml three necked flask. The reaction mixture is stirred under nitrogen at 50 °C for two days. The white solid formed is washed with diethylether and ethyl acetate, followed with filtration. The excess of solvents was removed by using rotary evaporator at 50 °C with reduced pressure. It was further dried by using vacuum oven for 2 days. The synthesis route is shown in Figure 3.3.

Figure 3.3: Synthesis route of [VBPPN][Cl]

3.3 Synthesis of the monomers, AAILs

All the starting material from [VBTMA][Cl], [VBTEA][Cl], [VBTBA][Cl], [VBMI][Cl] and [VBPPN][Cl] are subjected to anion exchange from Cl^- to OH^- and proceeded to neutralization process with amino acids.

3.3.1 Anion exchange from Cl^- to OH^-

10 g of the starting materials, [VBTMA][Cl] was dissolved in 200 ml of ethanol (or any solvents/water) until it was fully dissolved. The ILs solution was poured in a column chromatography filled with anion exchange resin, Amberlyst A26 (OH^- form). The resin, was filled into a column and aqueous [VBTMA][Cl] was passed through the resin. The resulting [VBTMA][OH] was collected dropwise with 1 drop in 10-15 seconds. The [VBTMA][OH] was then tested for residual Cl^- by silver nitrate (AgNO_3). The absence of Cl^- in the solution was confirmed with no white precipitate form. Similar procedure was used to exchange the Cl^- to OH^- for all the starting material.

3.3.2 Neutralization with amino acid

[VBTMA][OH] was neutralized with equimolar of amino acid (glycine, alanine, serine, proline, taurine, histidine, lysine or arginine). The amino acid was added to the

solution of [VBTMA][OH] and stirred for 1 day. The solvents (ethanol) were removed by using rotary evaporator 50 °C at low pressure. The excess of amino acids was precipitated out by adding proportions of acetonitrile and methanol in 7:3 ratio which gave white powder. This was then filtered out. The AAILs solution was further continued with rotary evaporator to remove all the solvents. The AAILs produced is a viscous ILs and store in a sample bottle and sealed. Similar procedure was used in neutralization process for [VBTEA], [VBTBA], [VBMI] and [VBPPN] cation. The synthesis route to synthesize the monomers is shown in Figure 3.4.

AA⁻ = glycine, alanine, serine, proline, taurine, histidine, lysine or arginine

Figure 3.4: Synthesis route of the monomers, AAILs with [VBTMA] as cation

3.4 Synthesis of amino acids polymerized ionic liquids (AAPILs)

In polymerization process, 10 g of the monomer [VBTMA][AA] (or any other cation), 100 mg AIBN and 5 ml of methanol are charge into three necked flask under nitrogen atmosphere and stirred. The flask is immersed in an oil bath at 65 °C for 1 day. The solid formed in flask was taken out and washed with methanol and dried in vacuum oven at 80 °C for 3 days. Similar procedure was used for the other cations and anions. The synthesis route to synthesized AAPILs from the monomer, AAILs, is shown in Figure 3.5

Figure 3.5: Polymerization of AAILs to AAPILs

3.5 Characterization of Ionic Liquids

The structures of all the starting materials were confirmed by using $^1\text{H-NMR}$. The characterization of AAILs and AAPILs was carried out using $^1\text{H-NMR}$, FTIR, Ultracyclopentimeter, Karl Fischer Coulometer, Ion Chromatography, Thermogravimetric analyzer, Differential Scanning Calorimetry, SEM and BET. The CO_2 sorption was carried out using gas absorption/adsorption cell.

3.5.1 Structure analysis

$^1\text{H-NMR}$ spectra was recorded on a Bruker Avance DRX-400 spectrometer operating at 400 MHz with deuterated methanol as solvents. The chemical shifts (δ) are reported in ppm. Multiplicities are abbreviated as follows; s for singlet, d for doublet, t for triplet, m for multiplet and br for broad.

FTIR was used to confirm the functional groups in AAPILs synthesized. FTIR was used to see the difference in functional groups before and after CO_2 sorption for AAPILs synthesized. FTIR spectra were recorded using Shimadzu FTIR in the region of $600\text{--}4000\text{ cm}^{-1}$ using Diamond Attenuated Total Reflectance (DATR measurement mode).

3.5.2 Density

The density of the synthesized AAPILs was determined by Ultrapycnometer 1000 Version 2.2 instrument using Argon gas. This instrument is designed for measuring the true volume and density of powders, foams and bulk solids. The samples ran for 6 times and the average is recorded with standard deviation $\pm 0.01 \text{ g/cm}^3$.

3.5.3 Water content

Water content for AAPILs was determined by Karl Fischer Coulometer model Mettler Toledo DL 39 attached with a Stromboli sample charger and the samples were heated to 150°C to determine the moisture in AAPILs solid.

3.5.4 Chloride content

The chloride content of [VBTMA][OH] was determined by ion chromatography (IC) Metrohm Model 761 Compact. The equipment used was equipped with Metrosep A Supp 5-150 (6.10006.520) (4.0 mm x 150 mm) analytical column and a Metrosep A Supp 4/5 guard column (4.0 mm x 5 mm). The eluent used is a mixture of 3.2 mM Na_2CO_3 and 1.0 mM NaHCO_3 . The data was analyzed with the aid of Metrodata IC Net 2.3 software.

3.5.5 Thermal stability

Thermal properties, degradation temperature (T_d), were measured using thermogravimetric analyzer (TGA) model Perkin Elmer Pyris 1, with heating rate of $40^\circ\text{C}/\text{min}$ and flow rate of nitrogen 20 ml/min. Glass transition temperature (T_g) was measured by differential scanning coulometric (DSC), Mettler Toledo model DSC 1 with heating rate $20^\circ\text{C}/\text{min}$ and flowrate of nitrogen 20 ml/min in temperature range from -130°C to 130°C . It was then cooled from ambient temperature to -130°C using liquid nitrogen. Then isothermal at -130°C for 2 minutes and continued with heating from -130°C to 130°C . The isothermal process was repeated for 2 minutes and the steps for second cycle were repeated for reproducibility.

3.5.6 Surface morphology

The morphology of AAPILs synthesized was determined by Scanning Electron Microscope (SEM), Variable Pressure Field Emission Scanning Electron Microscope (VPFESEM) model Zeiss Supra55VP. This morphology is to determine the topology structure of the sample whether the AAPILs have porous or nonporous structure. The magnification used is (300 to 5.00KX), working distance (3-6 mm) and accelerating voltage (2 to 5 kV).

3.5.7 Surface Area and Porosity (SAP) Analyzer

Surface area, pore size and pore volume of AAPILs before and after CO₂ sorption determined using surface area and porosity analyzer (Micromeritics TriStar II 3020). The SAP was calibrated using carbon black provided by Micromeritics. Before the measurement, 0.2 g sample in a sample cell was pretreated and degassed at 150 °C using N₂ for 3 hours. The purpose of this pretreatment is to remove any trapped moisture and impurities before the actual measurement. After the pretreatment process, the sample cell was tightened to the SAP system and immersed in a dewar filled with liquid N₂. The relative pressure (P/P_0) was set at 0.005-0.990, and the measurement completed in 8 hours.

3.6 CO₂ sorption measurement

The accuracy when measuring CO₂ solubility might be influenced by the purity of the gas since it will affect the results. Therefore, completely degassing the solvent prior to measurement is the most important step to ensure that the absorbed gas measured during the experiment is the true gas solubility.

In this research, all CO₂ absorption studies were measured by using a gas adsorption/absorption cell as shown in Figure 3.6. The system used is a volumetric type based on pressure drop method. Before the measurement, leakage test was done at 10 bar to ensure there was no pressure drop caused by the gas leakage from the equipment and also to avoid the inaccuracy during the measurement. The equipment was also tested using monoethanolamine (MEA) as control and compares the result

with literature data. The result shown 0.47 mol/mol slightly lower than the reported in literature which is 0.55 mol/mol [14].

For the measurement procedure, the sample was first dried overnight in the oven at 110 °C to remove any moisture before the adsorption. Initially, the pressure was adjusted by using valve A and valve B to obtain the desired pressure in the CO₂ storage tank (bomb). The cell was vacuumed for 15 minutes to remove any gas in the system. Then, 0.5-1.0 g of sample was placed in the sample cell and tightly attached to the system. Once the desired temperature and pressure were stable, the CO₂ was introduced to the ILs by releasing valve B and the pressure drop was recorded until the cell's pressure remained stable. The calculation to determine the mole of CO₂ captured is shown in Equation 3.1.

$$n = \frac{P_{ini} \cdot V_{tot}}{Z_{ini} \cdot R \cdot T_{ini}} - \frac{P_{eq}(V_{tot} - V_{sample})}{Z_{eq} \cdot R \cdot T_{eq}} \quad 3.1$$

where n = mol CO₂ captured, P_{ini} is the pressure obtained in the absence of a sample after expansion of the gas sample from the bomb into the whole system, V_{tot} = total of volume system (110 ml), Z_{ini} =compressibility factor ($P_{ini} \times T_{ini}$), Z_{eq} =compressibility factor ($P_{eq} \times T_{eq}$), P_{eq} =equilibrium pressure, V_{sample} =sample volume, $R=0.0821$ atm.L/mol.K, T_{ini} =initial temperature and T_{eq} =equilibrium temperature. The volume sample was measured by divided the mass of sample with density of the sample. The volume from valve A to valve B is 86.33 ml including the bomb volume. The compressibility factor was taken by using the *Peng-Robinson* equation of state (EOS). This EOS is use to predicting the vapour pressure and volumetric behaviour of single component systems and the phase behaviour and volumetric behaviour of the binary, ternary and multicomponent system. The *Peng Robinson* (1976) equation is shown at Equation 3.2.

$$Z = \frac{V}{V - b} - \frac{a}{RT[V + b + \frac{a}{RT(V - b)}]} \quad 3.2$$

Where Z is the compressibility factor ($Z = PV/RT$) where T is the temperature, V is volume, P is pressure and R is the molar universal gas constant. Parameter a is a measure of the attractive forces between the molecules, and the parameter b is the co volume occupied by the molecules. The a and b parameters can be obtained from the critical properties of the fluid. The *Peng-Robinson* (PR) equation of state slightly improves the prediction of liquid volumes and predicts a critical compressibility

factor of $Z_c=0.307$. This equation can be used to accurately predict the vapour pressures of pure substances and equilibrium ratios of mixtures. The advantage of this equation is that they can accurately represent the relation among the pressure, temperature and phase compositions in binary or multicomponent systems. To ensure the experimental data, all the experiments were repeated three times and standard deviation of CO_2 absorption data was less than 2 %.

Figure 3.6: Schematic diagram for gas absorption/adsorption cell

3.6.1 Adsorption Isotherm Measurement

Adsorption equilibrium is established when an adsorbate (gas) containing phase has been contacted with the adsorbent for sufficient time [127]. The interaction between adsorbate and adsorbent can be described by adsorption isotherm. This can explain the adsorption mechanism pathways, expression of the surface properties and capacities of adsorbents of adsorption systems [128].

The adsorption isotherm was carried out by studying the CO_2 sorption on AAPILs at various pressures (1, 3, 5, 7 and 10 bar) and at temperatures 298 K, 313 K and 333 K. Only the best AAPILs on capturing CO_2 capacity would proceed for the adsorption isotherm measurement. In this work, adsorption isotherm was carried out using Langmuir, Freundlich, Dubinin Radushkevich and Temkin isotherms and the best fitted model to describe the adsorption process was determined by the correlation coefficients (R^2) value [128].

Langmuir isotherm is commonly used for isotherm modelling and originally used to describe gas adsorption on AAPILs. Thus, this isotherm is the simplest model of physical adsorption which assumes monolayer adsorption where once a molecules occupies a site, no further adsorption can take place, no interaction between adsorbed adsorbate even on the adjacent site, and the enthalpy of adsorption is the same for each molecules [129].

The Freundlich equation is an empirical model that considers heterogeneous adsorptive energies on the adsorbent surface. In Freundlich isotherm, the adsorption is not restricted to the formation of monolayer [130]. This model can be applied to multilayer adsorption with non uniform distribution of adsorption heat and affinities over the heterogenous surface [131].

Dubinin-Radushkevich isotherm is an empirical model for the adsorption of subcritical vapors onto micropore solids which follows a pore filling mechanism [127]. This isotherm generally applied to the adsorption mechanism with a Gaussian energy distribution onto heterogenous surface [132].

The Temkin isotherm is usually used for heterogenous surface energy system (non uniform distribution of sorption heat) [133]. This isotherm also account for the adsorbent-adsorbate interactions. The model assumes that heat of adsorption (function of temperature) in the layer would decrease linearly rather than logarithmic coverage [132]. The non-linear and linearized equation of these isotherm models are summarized in Table 3.2.

Table 3.2: The non-linear and linearized equation of the isotherm models

Isotherm	Non-linear equation	Liner equation
Langmuir	$q_e = \frac{q_m K_L P_e}{1 + K_L P_e}$	$\frac{P_e}{q_e} = \frac{1}{K_L q_m} + \frac{P_e}{q_m}$
Freundlich	$q_e = K_F \cdot P_e^{\frac{1}{n}}$	$\log q_e = \log K_F + \frac{1}{n} \log P_e$
Dubinin-Radushkevich	$q_e = q_m e^{-\lambda \omega^2}$	$\ln q_e = \ln q_m - \lambda \omega^2$
Temkin	$q_e = B (\ln K_T P_e)$	$q_e = B \ln K_T + B \ln P_e$

Whereby for Langmuir: q_e is amount of CO₂ adsorbed per unit weight of adsorbent at equilibrium (mmol/g), q_m is maximum adsorption capacity (mmol/g), P_e

is equilibrium pressure (bar), K_L is Langmuir constant related to the free energy of adsorption (g/mmol). For Freundlich; K_F ($\text{mmol}^{1-(1/n)} \cdot \text{g}^{1/n} \cdot \text{g}^{-1}$) and n (dimensionless) is Freundlich constant related to the adsorption capacity and intensity. For Dubinin-Radushkevich; ω (J/mol) is the Polanyi potential (equivalent to $RT \ln(1+1/P_e)$), λ is D-R constant (mol^2/J^2). For Temkin; K_T ($\text{cm}^3/\text{g} \cdot \text{bar}$) is Temkin constant and $B=(RT/b_T)$ where b_T (J/mol).

3.7 COSMO-RS

The Conductor-like Screening Model for Real Solvents (COSMO-RS) is a well established method for the prediction of thermodynamic properties and phase behavior of pure chemical species and mixtures [134]. This COSMO-RS is used to predict qualitatively the gas solubility in ILs at the correct order of magnitude compared with the experimental data. This tool relies on combining the chemical calculations obtained by uni-molecular quantum theory and statistical thermodynamic principles. COSMO-RS methodology consists on processing the screening charge density, σ on the surface of molecules to calculate the chemical potential and activity coefficient of each species in the solution [135]. In this study, COSMO-RS is used to evaluate the CO_2 -capture ability of selected ILs having different combinations of cations and anions using the σ -profile analysis and σ -potential of the species involved. The solubility prediction of ILs by using COSMO-RS consists of two steps. The first step is a generation of COSMO-RS cation and anion files. The files were generated using BP functional B88-p86 with a triple- ξ valence polarized basis set (*TZVP*) and the resolution of identity standard (*RI*) approximation using the *TURBOMOLE 6.1* program package [136]. The second steps involves a statistical thermodynamics and were performed using *COSMOtherm*. The parameterization *BP_TZVP_C30_I301* (*COSMOlogic GmbH & Co KG, Leverkusen, Germany*) [137], which is required for the calculation of physicochemical data and contains intrinsic parameters of *COSMOtherm* and element specific parameters, was adopted. The chemical potential, μ_i is related to activity coefficient of component i , by

$$\gamma_i = \exp\left(\frac{\mu_i - \mu_i^o}{RT}\right) \quad 3.2$$

Where μ_i^0 the chemical potential of the pure compound i , R is the ideal gas constant and T the absolute temperature. In all calculations, ILs are always treated as equimolar mixture of cation and anion thus the scale by a factor of 0.5. The best predictions were obtained with the lowest energy conformations or with global minimum for both cation and anion. Thus in this work, the lowest energy conformations of all the species involved were used in the COSMO-RS calculations [134, 136, 138].

3.8 Density Functional Theory (DFT) Study of Amine Molecular

Density Functional Theory (DFT) modeling is to understand the role of amine in reactivity towards CO₂ by studying the variations in amine-CO₂ reaction energy of systematically different amines [139]. The present work focuses on the relationship between molecular properties of amines and their influence on the amine-CO₂ interactions. Molecular modeling within the framework of density functional theory (DFT) was used to evaluate the reaction energy to form the product species associated with the amine-CO₂ system [140, 141]. Conceptual DFT was used to relate electronic structure properties of the amines to trends in their reactivity, with the purpose of providing the foundational understanding to design of amine with target reactivities towards CO₂ [142].

The energy and electronic structure of the molecular systems were computed with DFT calculations using Gaussian 09 with the *B3LYP* functional and *6-31G** basis set. This *B3LYP* functional is sufficient to establish trends in molecular reactions of systems of the size considered in this study. Energy and electronic descriptor calculations were performed for a subset of the amines studied with a larger basis set *6-31G**, with no changes to the energy correlations, indicating that the level of theory with using *6-31G** was sufficient for the trends observed [143]. This functional and basis set is on average the best choice of a model chemistry for most systems and it is particular good for organic molecules, but less so for metal containing compounds [142]. The basic algorithm for the solution of DFT consists in self consistent loop at iteration, n :

The flowchart procedure of Kohn-Sham Self Consistent Field, KS SCF is shown in Figure 3.7 [144]. For instance, step 1 is to choose a basis set which is *6-31G**. After choose the molecular geometry, the overlap integrals and the kinetic energy and nuclear-attraction integrals are computed. To evaluate the remaining integrals, the initial density must to be guess to contstruct the V_{xc} and to evaluate the remaining integrals in each KS matrix element. New orbitals are determined from solution of the secular equation, the density is determined from those orbitals and it is compared to the density from the preceeding iteration. Once convergence of the SCF is achieved, the energy is computed by plugging the final density to optimize the molecular geometry. At this point, either the calculation is finished, or, of geometry optimization is the goal, a determination of whether the structure corresponds to a stationary point is made [144].

3.8.1 Thermochemistry output

The behavior of the molecules is governed by the empirically determined laws of thermodynamics such as enthalpy, entropy, free energy and others. The experimental convention for assigning a zero to an enthalpy or free energy scale is that this is the value that corresponds to the heat or free energy of formation associated with every element in its most stable, pure form under standard conditions (273 K, 1 atm). Thus, the meaning of an experimental heat of formation or enthalpy of formation for a molecule is the molar enthalpy change associated with removing each of the atoms in the molecule from its elemental standard state and assembling them into molecule [144]. To determine a standard state molecular thermodynamic quantity, the computed energy difference between the molecule and its constituent atoms is added to the experimental thermodynamic value determined for the identical atoms [145]. The usual way to calculate enthalpies of reaction is to calculate heats of formation and take the appropriate sums and difference as shown in Equation 3.3. The overall flowchart for the methodology is shown in Figure 3.8.

$$\Delta_r H^o \text{ } 298 \text{ K} = \sum_{\text{products}} \Delta_f H^o_{\text{prod}} \text{ } 298 \text{ K} - \sum_{\text{reactants}} \Delta_f H^o_{\text{react}} \text{ } 298 \text{ K} \quad 3.3$$

Figure 3.7: Flowchart of the KS SCF procedure

Figure 3.8: Flowchart for overall methodology

CHAPTER 4

RESULTS AND DISCUSSION

The characterization of AAPILs includes structure analysis such as ^1H -NMR and FTIR to confirm the structure synthesized. The chloride content and water content to ensure the purity of the synthesized AAPILs. Morphology analysis used to study the surface and porosity, the thermal stability such as degradation temperature and glass transition temperature to study the stability of AAPILs with temperature. All AAPILs and AAPILs synthesized are further studied for CO_2 sorption.

4.1 Identification and Structural Analysis of AAPILs and AAPILs

The ^1H -NMR result shows that the vinyl protons are seen at around 5.40 to 6.85 ppm in all monomers and as expected they do not appear in the polymeric compound; instead aliphatic protons are observed at 1.53 to 2.22 ppm. This indicates that the vinyl compounds were successfully polymerized. The benzylic protons and methyl protons on ammonium in the monomers also experienced upfield shifts, perhaps due to the effect of the neighboring cationic backbones in the polymer. All ^1H -NMR spectrum are shown in Appendix A. The ^1H -NMR peaks are shown in Table 4.1.

The polymerization of the monomer [VBTMA][Gly] successfully occurred when the vinyl group on the monomer has been shifted to upfield due to long alkyl group presence in the polymer. After polymerization also can be seen that all peaks of the monomers become broad due to the polymerization and low dissolution between polymer and solvent.

Table 4.1: ¹H-NMR peaks for AAILs and AAPILs

4.2 Functional Group Identification

FTIR characterization was carried out to study the presence of functional group in AAPILs. Figure 4.1 shows the comparison of FTIR spectrum, absorbance vs wavelength between the monomer of [VBTMA][Gly] and its polymer, poly[VBTMA][Gly].

Figure 4.1: FTIR spectrum for [VBTMA][Gly] and poly[VBTMA][Gly]

In Figure 4.1, the region 3300 cm^{-1} showed the presence of N-H amides. Region $3000\text{--}2900\text{ cm}^{-1}$ is typical for C-H. Peak 1570 cm^{-1} for COO^- group overlapped with N-H in amino acid. Therefore, at 1479 cm^{-1} is for benzene ring in aromatic compound and peak 1386 cm^{-1} is distinct for C-N group. The vinyl compound $\text{CH}=\text{CH}_2$ shows absorption at region 1000 cm^{-1} to 990 cm^{-1} . This region appears in the monomer [VBTMA][Gly] but not in the polymer. This shows that [VBTMA][Gly] is completely polymerized to poly[VBTMA][Gly].

Table 4.2 shows the FTIR peaks with functional group which confirmed the expected structure of the AAPILs. FTIR spectrums of AAPILs were shown in Appendix B. The characteristic FTIR peaks corresponding to C=O of the COO^- anion which mainly overlap with -NH from the amino acids at around $1610\text{--}1560\text{ cm}^{-1}$ with strong intensity. Broad peaks at around $3520\text{--}3320\text{ cm}^{-1}$ correspond to -NH of amines and the C-N stretch is observed at $1420\text{--}1375\text{ cm}^{-1}$. Based on Table 4.2

confirms the functional group presence in all AAPILs. The intensities are abbreviated as follows: *br* for broad, *s* for strong, *vs* for very strong and *m* for medium.

Table 4.2: FTIR peaks, intensity and functional groups of AAPILs

4.3 Physical Properties

The physical properties of AAPILs include chloride content, density and water content.

Chloride content of [VBTMA][OH] was determined by ion chromatography (IC) Metrohm model 761 compact. The result of chloride content for [VBTMA][OH] was negligible, which was 0.008 $\mu\text{S}/\text{cm}$. This showed that ionic liquids [VBTMA][Cl] was successfully exchange to hydroxide, [VBTMA][OH] by using anion exchange resin, Amberlyst A26 hydroxide (OH) form. This concentration of chloride is sufficiently low for application and should not have any effect on the physical properties of AAPILs. Figure 4.2 shows the ion chromatogram of chloride, Cl⁻ and the calibration curve is shown in Appendix B-14.

Figure 4.2: Ion Chromatogram of chloride, on [VBTMA][OH]

Physical properties such as water content, density, yield percentage (yield %), physical appearance, color and state form are shown in Table 4.3.

Table 4.3: Physical properties of AAPILs synthesized

AAPILs	Density (g/cm ³)	Water content (%)	Yield (%)	Color	Form
Poly[VBTMA][Gly]	0.8071	1.227	77.8	Yellowish	Solid
Poly[VBTMA][Ala]	0.7975	1.096	72.99	Yellowish	Solid
Poly[VBTMA][Ser]	0.7668	1.806	81.15	Brownish	Solid
Poly[VBTMA][Pro]	0.7685	1.285	60.31	Brownish	Solid
Poly[VBTMA][Tau]	0.8732	1.261	66.67	Yellowish	Solid
Poly[VBTMA][Hist]	0.8409	0.931	69.62	Yellowish	Solid
Poly[VBTMA][Lys]	0.7107	2.441	69.64	Yellowish	Solid
Poly[VBTMA][Arg]	0.7459	1.267	60.17	Yellowish	Solid
Poly[VBTEA][Lys]	1.0987	1.145	69.9	Brownish	Solid
Poly[VBTBA][Lys]	1.1216	1.524	71.6	Yellowish	Solid
Poly[VBMII][Lys]	1.2759	1.374	62.8	Brownish	Solid
Poly[VBPPN][Lys]	1.2870	1.286	66.2	Brownish	Solid

Table 4.3 shows the water content for most of the AAPILs is less than 2% except poly[VBTMA][Lys]. This water content of AAPILs was sufficiently high since the

amino acid can form hydrogen bonding with water though small amount of water was difficult to remove. The yield percentage of all AAPILs synthesized is low which within the range 60 – 70 %. This might be because of the long synthesise route from quaternization to anion exchange, neutralization and polymerization step make the loss of yield.

The densities were in the range of 0.7 – 0.8 g/cm³ in [VBTMA] based. These densities are lower than the monomeric forms reported in literature [70, 71, 98] due to the increment in free volume [3]. According to Zhang *et al.* [71], densities are also influenced by elongating the alkyl side chains of the [AA]⁻ which increases the free volume of ILs therefore decreasing the density. For example the density follows the order [Gly] > [Ala] > [Ser] > [Arg] > [Lys]. However the [Tau] anion shows a higher density of 0.8732 g/cm³ due to the heavier functional group of O=S=O in structure. Aromatic functionality also influences the density such that [Hist] and [Pro] have densities higher than the other anions with longer alkyl side chains.

When changing the alkyl chain length from [VBTMA] to [VBTEA] and [VBTBA], it can be seen that the densities increases from 0.7107 g/cm³ on poly[VBTMA][Lys] to 1.0987 g/cm³ on poly[VBTEA][Lys] and 1.1216 on poly[VBTBA][Lys]. This is similar reported in literature [3, 82] that densities on poly[VBTMA][BF₄] is 1.035 g/cm³ and increases to 1.225 g/cm³ on poly[VBTEA][BF₄]. By changing the cation from ammonium to imidazolium and piperidinium based, the density increases.. Poly[VBMI][Lys] shows higher density with 1.2759 g/cm³ and poly[VBPPN][Lys] with 1.2870 g/cm³. This might be because of the presence of aromatic functionality on imidazolium and piperidinium which increases the density.

4.4 Synthesis attempts of different backbone for polymerization

Different type of backbones were synthesized which is vinylbenzyltrimethylammonium [VBTMA], methacryloyloxyethyltrimethylammonium [METMA] and allybutylimidazolium [ABIM] as shown in Figure 4.3.

Figure 4.3: Different backbone of AAPILs

However, only vinyl backbone, [VBTMA], was successfully synthesized. For [METMA] backbone, the problem arised during anion exchange from [METMA][Cl] to [METMA][Gly]. This could be due to the anion exchange from Cl^- to OH^- .

From the ^1H -NMR spectra in Figure 4.4, can be seen that the methylmethacrylate group for [METMA][Gly] was disintegrated due to the reaction between OH^- with methylmethacrylate group thus form methacrylic acid. Therefore, [METMA] backbone is not suitable for process of anion exchange from chloride to hydroxide.

Figure 4.4: ^1H -NMR for (a) [METMA][Cl] and (b) [METMA][Gly]

For [ABIM] backbone, the polymerization of [ABIM] was failed and blackish color solution was formed and it seems like decompose occurred. Figure 4.5 shows ^1H -NMR with low integration after polymerized which explain the unsuccessful polymerization. It is believed that decomposition of [ABIM][Gly] occurred during polymerization at 65 °C as shown in Figure 4.6 Therefore, in this study only vinylbenzyl backbone were studied with various cations and anions.

Figure 4.5: ^1H -NMR for (a) [ABIM][Gly] (b) polymerized [ABIM][Gly]

Figure 4.6: TGA analysis for [ABIM][Gly]

4.5 Thermal stability on AAILs and AAPILs

Thermal stability is an important factor that determines the applicability of ILs for high temperature application. The stability of AAPILs can be determined in a function of temperature. In thermal stability, degradation temperature (T_d) and glass transition temperature (T_g) were studied. In order to evaluate the effect of structure on AAILs and AAPILs, T_d and T_g were studied which includes the effect of changing the anion, cation and alkyl chain length.

4.5.1 Effect of anion on thermal stability

To study the effect of anions on thermal stability, [VBTMA] cation was varied with different anions, [Gly], [Ala], [Ser], [Pro], [Tau], [Hist], [Lys] and [Arg]. Table 4.4 shows the thermal stability for AAILs and AAPILs synthesized with different anions and fixed [VBTMA] cation. TGA and DSC thermogram for the AAILs and AAPILs were shown in Appendix C.

Table 4.4: Degradation temperature (T_d) and glass transition temperature (T_g)

AAILs	T_d (°C)	T_g (°C)	AAPILs	T_d (°C)	T_g (°C)
[VBTMA] [Gly]	174	-68.3	Poly[VBTMA][Gly]	192	-46.5
[VBTMA] [Ala]	172	-57.2	Poly[VBTMA][Ala]	194	-34.7
[VBTMA] [Ser]	184	-66.2	Poly[VBTMA][Ser]	211	-38.5
[VBTMA] [Pro]	192	-46.1	Poly[VBTMA][Pro]	200	-26.5
[VBTMA] [Tau]	185	-51.5	Poly[VBTMA][Tau]	202	-23.9
[VBTMA] [Hist]	162	-14.6	Poly[VBTMA][Hist]	192	3.5
[VBTMA] [Lys]	166	-39.9	Poly[VBTMA][Lys]	191	-1.7
[VBTMA] [Arg]	170	-27.1	Poly[VBTMA][Arg]	185	-5.9

Table 4.4 shows that degradation temperature, T_d of AAILs with different anions varied from 162 °C to 192 °C. This is lower than the values for the same anions with different cations reported by Goodrich *et al.* (2011), [96] by using $[P_{66614}]^+$ as cations

and $[aP_{4443}]^+$ as reported by Zhang *et al.* (2009) [71]. As well as cation, the structures of $[AA]^-$ also have a big effect on T_d and T_g values. The $[AA]^-$ with active functional groups and have high negative charge density would lower the T_d values [71]. Anions with amine functional groups; [His], [Lys] and [Arg] have low T_d values from 162 to 170 °C than anions with single amine groups; [Ala], [Gly], [Ser], [Tau] and [Pro] which have high T_d values from 172 to 192 °C.

From Table 4.4, it can also be seen that after polymerization all T_d of AAILs increases about 10 to 30 °C. Polymerization increased the thermal stability of AAILs. Similar with AAILs, it also shows that anions play a significant role in determining the T_d values. Polymerization helped to increase the thermal stability of AAILs. Same trend can be observed in AAPILs where anions [Arg], [Lys] and [Hist] have low T_d values from 185 to 192 °C and anions [Gly], [Ala], [Pro], [Tau] and [Ser] have higher T_d values from 192 to 211 °C.

In contrast with T_d values, better flexibility of $[AA]^-$ with short and linear alkyl side chains lowers the T_g values. Anions [Gly], [Ser], [Ala] have lower T_g values from -46.5 to -34.7 °C. These anions have smaller side chain which lowers the T_g values. On the other hand, anions with ring in the side chain, long alkyl side chain of $[AA]^-$ have higher T_g values from -26.5 to 3.5 °C corresponding to [Pro], [Tau], [Arg], [Lys] and [Hist] anions. For [Pro] anion, it has pentagonal ring as a side chain and for anions [Tau], [Arg] and [Lys], these anions have longer alkyl side chain and contain numbers of functional group. For [Hist], it has longer alkyl side chain as well with aromatic ring in a side chain therefore, the T_g is higher than others. Similar trends can be observed with monomers where [Gly], [Ser], [Ala] have lower T_g than [Tau], [Pro], [Lys], [Arg], and [Hist]. These trends of T_d and T_g corresponds to findings by Zhang *et al.* [71] with using $[aP_{4443}]^+$ as cation.

Similar with T_d values, after polymerization, the T_g values increases with 30 to 40 °C. This increasing trend of T_d and T_g are due to strong intermolecular bonds in polymers chain, which have higher value of cohesive energy density [146].

4.5.2 Effects of cation on thermal stability

To study the effect of cation on thermal stability of AAILs, lysinate [Lys] anion was varied with different of cation; [VBTMA], [VBTEA], [VBTBA], [VBMI] and

[VBPPN]. The trend of T_d on AAILs with different of cation follows [VBMI] (217 °C) > [VBPPN] (185 °C) > [VBTMA] (166 °C).

By changing the alkyl chain length on cation, it can be seen that the T_d increases from methyl, [VBTMA] (166 °C) < ethyl [VBTEA] (195 °C) < butyl [VBTBA] (203 °C). Cao *et al.* [147] reported that increasing the side chain of the cation will result in decreasing the ILs thermal stability. This reduction in the T_d could be due either to the decrease in intermolecular interaction or to the initial decomposition of the alkyl substituent. However, there were exceptions as reported by many researchers. Nawshad *et al.* (2014), [148] reported that T_d increases as increasing alkyl chain length from methyl to butyl due to increase of mass loss. Similar observation trend supports by Zhang *et al.* (2013), [114] that [bis(mim)C₄]²⁺ was 40 °C higher than [bis(mim)C₂]²⁺ when paired with same [AA]⁻ anion due to the asymmetric structures of the cation that increased the thermal stability.

By polymerizing the AAILs, the T_d increased compared to monomers as shown in Table 4.5. This correspond to the trend reported by Zhang *et al.* (2013) and Cao *et al.* (2014) [95, 147], that imidazolium is more stable ILs than ammonium cation. After polymerization, imidazolium still gave the highest degradation temperature than others cation. This might be due to the imidazole structure is resistant to ring fission during thermal rearrangement at higher temperature [149-151].

Table 4.5: Thermal stability on AAPILs with different cation and fixed [Lys] anion

AAILs	T_d (°C)	T_g (°C)	AAPILs	T_d (°C)	T_g (°C)

[VBMI][Lys]	217	-44.4	Poly[VBMI][Lys]	227	-33.3
[VBPPN][Lys]	185	-50.5	Poly[VBPPN][Lys]	202	-44.4

For T_g value, the results showed the T_g on AAILs increases as alkyl chain length increase. This is because the T_g was associated with the cohesive force between the ions which mainly determined by the molar volume. At low molar volume, the force is dominated by attractive Coulomb forces between the ions which decrease with

increasing molar volume. At larger molar volumes, van der Waals starts to dominate which lead to increasing T_g . The molar volume increases with increasing of alkyl chain length attached to cation can significantly increase T_g values [152]. Thus, via the influence on cohesive forces and the value of T_g in the van der Waals regime, the alkyl chain plays an important role in the molecular mobility. According to Michael *et al.* [152], the T_g increase with increasing alkyl chain length until, $n=10$.

On the contrary with polymerized, AAPILs, the T_g decreases with increasing of alkyl chain length. This caused by higher surface area of the polymer due to amorphous structure thus lower the T_g values. These T_g results give a good indication of the degree of amorphous nature of the polymer and further the surface area of polymer. The T_g results also shows an indication that AAPILs are amorphous as there is no melting or crystalline peak in DSC plot. Tang *et al.* (2009) [82] reported that the plasticization reduces the T_g leads to decrement in microvoid fraction of the PILs. This trends also similar reported with Mohamed *et al.* (2011) [3] that T_g for poly[VBTMA][NO₃] (167 °C) is higher compared to poly[VBTEA][NO₃] (105 °C). The reduction of T_g has been attributed to increases of flexibility due to long alkyl chains and also the reduction in lattice energy [90].

After polymerization, the T_g increases compared to the monomer. The polymerization of AAILs enhanced the thermal stability. It can be concluded that the structure of the anions are the factors that influences the thermal stability of AAILs and AAPILs. By changing the anion, the thermal stability is greatly affected than cation modification [147].

4.6 Morphology Micrograph

All the SEM micrograph can be seen in Appendix D. From the Appendix D, the SEM micrographs showed that some of AAPILs synthesized *i.e.* poly[VBTMA][Gly], poly[VBTMA][Ser] and poly[VBTMA][Pro] showed an even surface where as other AAPILs showed an uneven surfaces thus gave higher surface area.

Figure 4.7: SEM images for AAPILs synthesized

Figure 4.7 shows SEM images for (a) poly[VBTMA][Tau], (b) poly[VBTMA][Hist], (c) poly[VBTMA][Lys] and (d) poly[VBTMA][Gly]. These AAPILs are predicted to give higher CO₂ sorption as their surface area can host CO₂. However Poly[VBTMA][Gly] showed even structure. If the topology structure by means of surface area of AAPILs plays a great role in CO₂ sorption capacity, then these three AAPILs (a,b and c) should gave higher CO₂ sorption than poly[VBTMA][Gly] as their surface area to host the CO₂ is higher than poly[VBTMA][Gly].

Table 4.6 shows the BET analysis before and after CO₂ sorption. It can be seen that after CO₂ sorption, the BET surface area and pore volume are lower than before CO₂ sorption due to physical adsorption occurred in the surface of poly[VBTMA][Lys]. In physical adsorption, the CO₂ are trapped in the pore hence it gives lower pore volume and decreases the surface area. However, most of AAPILs are non porous solid therefore, only poly[VBTMA][Lys] applicable for BET analysis. AAPILs with uneven surface give higher surface area plays a role in physical adsorption with CO₂.

Table 4.6: Textural analysis before and after CO₂ sorption on poly[VBTMA][Lys]

	Before CO ₂	After CO ₂
BET surface area (m ² /g)	2.360	1.284
Pore volume (cm ³ /g)	0.003	0.002

4.7 Carbon Dioxide Sorption

Carbon dioxide sorption of the AAILs and AAPILs is measured with standard methods. The polymerization, anion, cation, alkyl chain length of cation, pressure, temperature, presense of water, comparison of gases and recyclability of AAPILs were studied. Tables of all CO₂ sorption can be found in Appendix E.

4.7.1 Comparison of CO₂ sorption capacities with MEA, RTILs, AAILs and AAPILs

To compare the efficiency of RTILs, AAILs and AAPILs towards CO₂ sorption, the CO₂ sorption were studied at 1 bar and 298 K by using the gas adsorption/absorption cell. Figure 4.8 shows the CO₂ uptake of the AAILs ([VBTMA][Arg]), AAPILs (Poly[VBTMA][Arg]), RTILs ([BMIM][Cl]) and with MEA as a control sample.

Figure 4.8: CO₂ sorption on AAILs, AAPILs, RTILs and MEA

From Figure 4.8 can be seen that the MEA sorption data obtained is 0.47 mol/mol slightly lower than that reported in the literature (0.55 mol/mol) for a THF solution of MEA [14]. MEA was run as control sample to ensure that results from the equipment for CO₂ sorption are reliable. In Figure 4.8 shows that the comparison of CO₂ sorption by using different type of samples *i.e.* MEA, RTILs, AAILs and AAPILs.

The results showed that CO₂ sorption for the AAILs is much higher with 0.83 mol/mol compared with [BMIM][Cl] with 0.03 mol/mol as the latter is exhibits only physical adsorption. This result confirms that ILs with amine functionality tethered to the anion exhibit enhanced CO₂ sorption due to a chemical absorption mechanism.

Polymerization of the AAILs led to an increase in CO₂ uptake. This has been suggested is due to the increased free volume in the polymer material. The high surface area of the powdered polymer samples enhanced the rate of CO₂ uptake. The highest absorption achieved for Poly[VBTMA][Arg] was 1.14 mol/mol. These values are higher than those reported by Tang *et al.* (2005) [81], (poly[VBTMA][BF₄] gave 0.102 mol/mol) , indicating the substantial role of the amino acid anions in the absorption. Poly[VBTMA][Arg] achieved 76% capacity in

30 min higher than [VBTMA][Arg], [BMIM][Cl] and MEA with 67 %, 25 % and 36 % sorption capacity respectively.

However, since AAPILs are not fully dissolved in any solvent, therefore the degree of polymerization (DP) is difficult to be measured. According to Osman *et al.* (2011) [3], reaction time during polymerization process would give different molecular weight with 11,518 (6 hours) and 21,531 (12 hours). Therefore, poly[VBTMA][Pro] was synthesized at two different polymerization times at 6 hours and 24 hours. Their degradation temperatures, T_d were measured as shown in Figure 4.9.

Figure 4.9: Degradation temperature on poly[VBTMA][Pro] at 6h and 24h

From Figure 4.9, the T_d on poly[VBTMA][Pro] at 24 hour reaction was 200 °C which is higher than T_d temperature at 6 hour (173 °C). In general, polymer with higher DP gave higher T_d . Thus, this indicates that these two batches of poly[VBTMA][Pro] is having different number of DP. However, even though the DP is different, these two batches of poly[VBTMA][Pro] still shows almost similar CO₂ sorption capacity with 0.60 mol/mol (6 h) and 0.62 mol/mol for 24 h as shown in Figure 4.10. This is because, the capacity of CO₂ sorption on polymer only depended on the monomer regardless the DP of polymer.

Figure 4.10: CO₂ sorption on poly[VBTMA][Pro] at 6h and 24h reaction times

4.7.2 Effects of anion on CO₂ sorption

The solubility of a gas is governed by a combination of factors namely: polarizability of the gas, the dispersion forces and the interactions between the gas and solvent. The relative influence of each of these factors differs with the nature of the gas and the solvent involved. Several studies reported that CO₂ solubility in ILs depends primarily on the strength of interaction of CO₂ with anion [153].

To study the effect of anion type on AAPILs and AAILs, the CO₂ sorption capacity with [VBTMA] and various anions were studied at 1 bar pressure at 298 K. Table 4.7 shows the CO₂ uptake on all AAILs and AAPILs synthesized.

In AAPILs, [Arg] and [Lys] have higher CO₂ sorption with 1.14 mol/mol and 1.13 mol/mol respectively. Followed with [Hist], [Ser], [Tau], [Pro], [Gly], [Ala]. This is mainly because arginine, [Arg], comprises of two primary amines and two secondary amines and [Lys] comprises of two primary amines. Thus, the accessibility of CO₂ to react with one or more of these amine sites is an advantage [70].

Table 4.7: CO₂ absorption on AAILs and AAPILs with fixed [VBTMA] cation

AAILs	Mol CO ₂ / mol monomer	wt %	AAPILs	Mol CO ₂ / mol monomer	wt %
[VBTMA][Gly]	0.47	8.32	Poly[VBTMA][Gly]	0.60	10.63
[VBTMA][Ala]	0.29	4.84	Poly[VBTMA][Ala]	0.56	9.05
[VBTMA][Ser]	0.39	6.07	Poly[VBTMA][Ser]	0.68	10.56
[VBTMA][Pro]	0.38	5.72	Poly[VBTMA][Pro]	0.62	9.30
[VBTMA][Tau]	0.44	6.50	Poly[VBTMA][Tau]	0.64	9.34
[VBTMA][Hist]	0.46	6.10	Poly[VBTMA][Hist]	0.80	10.62
[VBTMA][Lys]	0.66	9.05	Poly[VBTMA][Lys]	1.13	15.68
[VBTMA][Arg]	0.83	10.49	Poly[VBTMA][Arg]	1.14	14.23

Histidine, [Hist] which has one primary amine and one secondary amine in a ring, has less accessibility for CO₂ with 0.80 mol/mol. [Gly], [Ala], [Ser], [Pro] and [Tau] which has one amine group gave 0.60, 0.56, 0.68, 0.62 and 0.64 mol/mol respectively. The CO₂ sorptions in all AAPILs are higher and all are above 0.5 mol/mol whereas [Arg] and [Lys] obtained more than 1.0 mol/mol which achieved the mechanism of 1:1.

For poly[VBTMA][Arg], it is higher with 37% from the monomer, [VBTMA][Arg]. The trend for AAILs are almost similar with AAPILs, where [Arg] has the highest CO₂ sorption with 0.83 mol/mol and [Lys] with 0.66 mol/mol followed with [Gly], [Hist], [Tau], [Ser], [Pro] and [Ala]. This is lower than AAPILs since in AAPILs, both physical and chemical absorption are involved. When amine is attached to the anion of the IL, carbamate species forms, but there is a possibility that the negatively charged functionality on the anion can take up the proton released upon CO₂ capture thus forming carbamic acid [68]. The CO₂ can be absorbed with a stoichiometry of up to 1:1, meaning much more efficient use of the IL. The uptake of CO₂ by this chemical mechanism is described in Equations 4.1 and 4.2. Amino acids [AA]⁻ have structure of [H₂N-CHR-COO⁻], they are represented here as R⁻ NH₂.

Theoretical calculations showed that the dianion formed in the equation 4.2 is chemically unstable therefore the reaction would expect to terminate at equation 4.1 upon addition of CO₂ to AAILs. This indicates a potential absorption stoichiometry of 1:1 (CO₂: IL). Since several of the AAILs show CO₂ uptake > 0.5 mol/mol, *e.g* [VBTMA][Arg] at 0.83 mol/mol, as hypothesized that maximum of 1:1 may be achievable.

These results are similar in the literature that AAILs with more than one amine site have shown higher CO₂ sorption capacity than the AAILs with only one primary amine group. Sistla *et al.* [70], reported that [bmim][Arg] shown more CO₂ sorption with 0.62 mol/mol followed with [bmim][Lys] with 0.48 mol/mol due to the availability of more accessible amine groups. Saravanamurugan *et al.* [105] reported that ammonium based, [N₆₆₆₁₄][Arg] shows high CO₂ sorption with 1.0 mol / mol.

The interaction between the PILs with CO₂ can be explained based on the anion. It was suggested anion has a significant role in governing the CO₂ sorption [74]. This is because, amino acids *i.e.* [Arg], [Lys] and [Hist] are basic amino acids because they contain basic side chains. The interaction of anions and CO₂ is expected to be stronger than non amino acids anions [70]. Figure 4.11 shows the CO₂ sorption of AAPILs with different anions at 1 bar, 298 K.

It can be concluded that with bigger number of amine group in ILs structure, the more CO₂ have been absorbed [118]. The CO₂ interactions between cation/anion with CO₂, also depends on the intermolecular forces and also accessibility of amine group.

Figure 4.11: CO₂ sorption on AAPILs with different anions

With the aim of understanding the CO₂-ILs interaction, the knowledge of CO₂ behaviour in the pure state as well in the mixtures of ILs is important. This is to confirm the interaction between CO₂-ILs. Therefore, the molecular behavior of CO₂ and the type of molecular interactions can be explained by activity coefficient and σ -profiles by using COSMO-RS.

4.7.2.1 Activity coefficient at infinite dilution, γ_s^∞ by COSMO-RS

To understand the ILs-CO₂ interaction, activity coefficient, γ_s^∞ was carried out to evaluate the effect of the structural characteristics of ILs on the activity coefficient of CO₂ at infinite dilution in ILs, γ_s^∞ . The activity coefficient, γ_s^∞ of CO₂ towards the ILs can be determined by COSMO-RS predictions as presented in Table 4.8. In addition, the experimental data were used to evaluate the reliability of the COSMO-RS model in describing the γ_s^∞ of these systems [154]. During the calculations, the cation and anion of ILs were treated as equimolar mixture, thus it allows to study the contribution of each counterion on their affinity toward the CO₂ molecule [155]. The lowest energy conformation gives the best prediction [154].

Table 4.8: Activity coefficient, γ_s^∞ of CO₂ in ILs

ILs	Activity coefficient, γ_s^∞	CO ₂ sorption (mol/mol)
[VBTMA][Arg]	0.2799	0.83
[VBTMA][Lys]	0.2816	0.66
[VBTMA][Gly]	0.2841	0.47
[VBTMA][Hist]	0.3020	0.46
[VBTMA][Ala]	0.3049	0.29

The lower activity coefficient will lead to higher interaction between the solute and solvent thus give higher CO₂ sorption. The solubility trend of CO₂ and anions observed is similar to the activity coefficient trend described above. Based on Table 4.8, can be seen that decreasing interaction with CO₂ is [VBTMA][Arg] > [VBTMA][Lys] > [VBTMA][Gly] > [VBTMA][Hist] > [VBTMA][Ala]. This trend has a good agreement with experimental results that [VBTMA][Arg] showed the highest CO₂ sorption capacity with 0.83 mol/mol and [VBTMA][Ala] gave the least CO₂ sorption capacity with 0.29 mol/mol. The interaction between CO₂ and anions, [Arg] and [Ala] can be explained by σ -profile [136].

4.7.2.2 σ -Profile of CO₂ and anions, [Arg] and [Ala]

COSMO-RS allows analyzing the behavior of a molecule in both its pure and mixture states. Therefore, the quantum chemical calculations, COSMO-RS use 3D molecular surface polarity distributions to calculate the thermodynamic properties of compounds [138]. Data can be easily envisioned in the histogram function called σ profile. Figure 4.12 present the σ -profile for the studied CO₂ and anions, [Arg] and [Ala].

Figure 4.12: σ -profile of CO_2 , [Arg] and [Ala] as computed by COSMO-RS

From Figure 4.12, the COSMO-RS histogram is generally divided into three main regions. The first region is hydrogen bond donor region where $\sigma < -1 \text{ e.nm}^{-2}$. The second region is between $-1 < \sigma < 1 \text{ e.nm}^{-2}$ and it is related to the non-polar behavior of molecule. The third region is molecule's ability to act as hydrogen bond acceptor where it lies at $\sigma > 1 \text{ e.nm}^{-2}$ [156]. In Figure 4.12, the σ -profile of CO_2 presents a series of peaks within the non-polar region only. This indicates that CO_2 is highly non-polar.

Thus, a general rule can be drawn from the σ -profile that CO_2 is likely to interact with nonpolar groups of other molecules due to '*like dissolve like*' interaction between solute and solvent [156]. From Figure 4.12 can be seen that [Arg] is highly non polar compared to [Ala]. Therefore, the interaction between [Arg] with CO_2 is higher compared to [Ala]. This explains the higher solubility of CO_2 in [Arg]. In addition, the anions, [Arg] and [Ala] also has a peak in H-bond acceptor ($\sigma > 1 \text{ e.nm}^{-2}$) and H-bond donor ($\sigma < -1 \text{ e.nm}^{-2}$) due to the presence of COO^- and NH_2 in amino acids respectively.

Hence, it can be concluded that nonpolarity plays a significant role in the interaction of ILs with CO_2 [134, 138, 156]. Thus the affinity of CO_2 is increasing

toward more non polar ILs. Therefore, ILs with high polarity display less interaction toward CO₂ [137, 156, 157].

4.7.3 Effects of cation on CO₂ sorption

To study the effect of cation on CO₂ sorption capacity, the sorption of AAPILs with fixed anion, lysinate, [Lys] and various cation *i.e.* ammonium, [VBTMA], imidazolium [VBMI], and piperidinium [VBPPN] were studied at pressure 1 bar, 298 K. Lysinate [Lys] has been chosen because [Lys] and [Arg] both showed tremendously CO₂ uptake. The results are shown in Figure 4.13 and Table 4.9.

Figure 4.13: CO₂ sorption on different cation with fixed [Lys] anion at 1 bar, 298 K

At equilibrium, poly[VBTMA][Lys] absorb 1.13 mol/mol, higher than poly[VBPPN][Lys] with 0.99 mol/mol and poly[VBMI][Lys] with 0.82 mol/mol. It can be seen that ammonium cation gave higher CO₂ sorption than piperidinium while imidazolium have the least CO₂ sorption. This follows the trend reported by Tang *et al.* [82], where ammonium gave higher CO₂ sorption and imidazolium gave the lowest CO₂ sorption. This suggesting that ammonium cation had the strongest interaction with CO₂ and imidazolium cation had the weakest [82].

Table 4.9: CO₂ sorption of different cation with [Lys] as anion

AAILs	Mol CO ₂ /mol monomer	Wt%	AAPILs	Mol CO ₂ /mol monomer	Wt%
[VBTMA][Lys]	0.66	9.05	Poly[VBTMA][Lys]	1.13	15.68
[VBTEA][Lys]	0.62	7.45	Poly[VBMI][Lys]	0.82	10.44
[VBTBA][Lys]	0.62	6.60	Poly [VBPPN][Lys]	0.99	12.11
[VBMI][Lys]	0.44	5.63	Poly[VBTEA][Lys]	0.87	10.7
[VBPPN][Lys]	0.65	7.78	Poly[VBTBA][Lys]	0.72	7.63

By changing the alkyl chain length of ammonium from methyl, to ethyl and butyl, it can be seen that the CO₂ sorption decreases as shown in Figure 4.14.

Figure 4.14: CO₂ sorption on different of alkyl chain length

From Figure 4.14, it can be seen that the trend decreases with poly[VBTMA][Lys] (1.13 mol/mol), poly[VBTEA][Lys] (0.89 mol/mol) and poly[VBTBA][Lys] with 0.72 mol/mol. The long alkyl substituents on the cation reduce the CO₂ sorption capacity. The longer alkyl chain may hinder the interaction between CO₂ and the cation due to steric effects. This trends is similar reported by Tang *et al.* (2009) [82], where poly[VBTEA][BF₄] gave lower CO₂ sorption than

poly[VBTMA][BF₄]. Osman *et al.* (2011) [3] reported that poly[VBTMA][NO₃] gave higher CO₂ uptake with 0.22 mol/mol compared to poly[VBTEA][NO₃] with 0.15 mol/mol.

4.7.4 Effect of pressure

To study the effect of pressure, the CO₂ sorption using [VBTMA] incorporating [Arg], [Lys], [Hist], [Gly] and [Ala] were studied. The CO₂ sorption was carried out at 298 K and pressures 1, 3, 5, 7 and 10 bar as shown in Figure 4.15. Table 4.10 shows the reported data.

Figure 4.15: CO₂ sorption with increasing pressure at 298 K

It can be seen that the CO₂ sorption increases with increasing pressure for all five AAPILs with [VBTMA] as the cation. This is expected since when pressure increase, it will force the gas into the ILs [158]. From Figure 4.15, the CO₂ molar uptake increases continuously with increasing pressure under studied conditions. At low pressure, a large uptake of CO₂ is due to the chemical absorption process and the further increase at higher pressure is due to physical adsorption [96]. This shows how

the sorption performances of AAPILs merge the characteristics of physical adsorption with the attractive features of chemical absorption [22]. Sistla *et al.* [70] have reported that the CO₂ capacity on AAILs increases with increasing pressure which ranging from 0.32 to 0.82 mol/mol in the pressure range from 1-10 bar. They reported that the mechanism of 1:1 only achieved at 4 bar pressure. However, these reported results are lower since the latter is in monomeric form.

Table 4.10: CO₂ sorption on AAPILs at different pressure and temperature at 298 K

AAPILs	CO ₂ sorption (mol/mol)				
	1 bar	3 bar	5 bar	7 bar	10 bar
Poly[VBtMA][Arg]	1.14	1.52	1.93	2.13	2.77
Poly[VBtMA][Lys]	1.13	1.26	1.64	2.06	2.75
Poly[VBtMA][Hist]	0.8	1.23	1.32	1.76	2.31
Poly[VBtMA][Gly]	0.6	0.76	1.06	1.35	1.71
Poly[VBtMA][Ala]	0.56	0.87	0.91	1.16	1.25

In general, increasing pressure is proportional to increase in gas concentration. More number of gas molecules are getting contacted with ILs, thus increases the sorption of CO₂ [92]. In a typical physisorption isotherm, the amount of CO₂ adsorbed increases with the system pressure. The gas fills the free spaces in the ILs, interacting with its ions [159], without significantly affecting the structure of the ILs [160]. To confirm the physical adsorption also involved in AAPILs at higher pressure, BET isotherm model was used to deal with adsorption process.

4.7.4.1 The Brunauer-Emmett-Teller (BET) Model

The most widely used isotherm dealing with multilayer adsorption was derived by Stephen Brunauer, Paul Emmet and Edward Teller (BET). This model mostly applied in gas-solid equilibrium system [127]. BET model was used to determine the

isotherm by plotting the CO₂ adsorb capacity, mmol/g against relative pressure, P/P^o , where P is the equilibrium pressure and P^o is the saturated vapour pressure as shown in Figure 4.16.

Figure 4.16: BET physisorption isotherm on poly[VBTMA][Arg] at higher pressure

In Figure 4.16, BET model shows the type II isotherm. This isotherm is produced by non-porous solid and it does not limited in the monolayer at the adsorbent surface but can also formed multilayer [161]. Kim *et al.*(2016) [162] also reported that BET model showed multilayer formation when using metal organic framework (MOFs) with CO₂ adsorption isotherm. There is a point B that shows at which monolayer coverage complete and multilayer of adsorbed is about to commence. At low relative pressure, formation of monolayer of adsorbed molecules is the prevailing process, while at high P/P^o , a multilayer adsorption take place [163]. The expression of BET model adsorption isotherm shown in equation 4.3

$$\frac{P}{n(P^o - P)} = \frac{1}{n_m C} + \frac{C - 1}{n_m C} \left(\frac{P}{P^o} \right) \quad 4.3$$

Where P is the equilibrium pressure and P^o is the saturated vapour pressure, n is the adsorption capacity and n_m is the monolayer capacity and C is the BET constant [163]. A plot of $\frac{P_e}{n(P^o - P)}$ against $\frac{P}{P^o}$ was plot and a straight line between P/P^o values from about 0.05 to 0.3 indicates monolayer formation as shown in Figure 4.17.

Figure 4.17: BET isotherm model plot

Figure 4.17, shows a BET plot for a given adsorption isotherm. Based on the plot, the adsorption of monolayer capacity, n_m and the BET constant, C can be calculated [162]. The calculation shows that the monolayer capacity, n_m or the quantity of gas adsorbed when the entire surface is covered with monomolecular is 4.764 mmol/g and the BET constant calculated is 3.619.

Therefore, by plotted the BET model as described above, can be concluded that physical adsorption with multilayer formation occurred in AAPILs when pressure increased.

4.7.5 Effect of Temperature

To study the effect of temperature, the CO₂ sorption of poly[VBTMA][Arg] were studied at 25, 30, 35, 40, 60 and 80 °C at 1 bar pressure as a function of time as shown in Figure 4.18 and Table 4.11 are reported data.

Figure 4.18: CO₂ sorption at different temperatures

Table 4.11: CO₂ sorption on poly[VBTMA][Arg] at different temperatures

Temperature (°C)	Mol/mol	Wt %
25	1.14	14.23
30	1.10	13.95
35	1.09	13.74
40	0.69	5.40
60	0.33	4.21
80	0.01	0.16

Figure 4.18 shows at higher temperatures, 40 °C to 80 °C, it took faster to achieved equilibrium since the desorption process occurred. Hence, at Figure 4.19, it can be seen that at room temperature, the CO₂ sorption is saturated and a plateau as function of temperature exists between 25 to 35 °C with little effect of temperature. Temperature has a great impact on CO₂ sorption capacity. By increasing the temperature, a serious reduction in CO₂ sorption capacity can be noticed. At 40 °C, the adsorption capacity is much lower indicating that the adsorption equilibria is shifting towards the desorbed as expected since desorption is endothermic.

Desorption temperature as low as 30 °C have been observed previously for protic ionic liquids [88].

Figure 4.19: CO₂ sorption on poly[VBTMA][Arg] at different temperature

4.7.6 Recyclability of AAPILs

Environmental considerations require the recovery of ILs after their use. Since ILs are quite expensive, hence by recycling the ILs are necessary due to economic reasons. Since fully desorption of poly[VBTMA][Arg] occurred at 80 °C, therefore the recycling process carried out at 80 °C through depressurization in vacuum oven for 24 hours. The samples were run for the next cycle to see the recyclability of AAPILs. Figure 4.20 shows the recyclability of poly[VBTMA][Arg].

Figure 4.20: Recyclability of poly[VBTMA][Arg]

In the first cycle, CO₂ capture is 1.14 mol/mol. Poly[VBTMA][Arg] was then taken out for regeneration process. After the first desorption, the CO₂ removal is not completely achieved in desorption process therefore in second cycle, the CO₂ sorption reduced slightly to 1.02 mol/mol. By repeating the procedure for 5th cycle, the CO₂ sorption was still high at 0.98 mol/mol. The difference between of sorption from 1st cycle to 5th cycle after desorption might be due to an initial structural reorganization taking place within the ILs during the 1st cycle sorption [105]. This shows that AAPILs are very stable and can be use up until 86 % sorption in 5th cycle to get approximately 1 mol CO₂ captured per mole of monomer.

To study the regeneration of ILs, we studied the FTIR spectrum after the sample regenerate at 80 °C. Figure 4.21 is the FTIR spectrum before CO₂ sorption, after CO₂ sorption and after regenerate at 80 °C on poly[VBTMA][Arg].

Figure 4.21: FTIR spectrum on poly[VBTMA][Arg]

After CO₂ sorption, the amine in anion reacted with CO₂ and formed carbamic acid. From Figure 4.21, after CO₂ sorption, the range 3346 – 3188 cm⁻¹ shows an overlapped peak on N-H secondary and -OH formed in carbamic acid. The peak with high intensity formed in 1639 cm⁻¹ and 1560 cm⁻¹ corresponds to C=O in secondary amide and NH formed in carbamic acid respectively. However, after regeneration of poly[VBTMA][Arg] with CO₂ at 80 °C, the FTIR shows the intensity of C=O is reduced and the shoulder shows around 1600 cm⁻¹ indicates the overlapped of COO⁻ and NH₂ in amino acids. After regeneration, the newly bound carbamic acid onto poly[VBTMA][Arg] would release the CO₂ molecule from poly[VBTMA][Arg]. Therefore the samples are ready for next cycle CO₂ sorption.

4.8 Adsorption Isotherm

Since the CO₂ sorption on AAPILs involved a physical adsorption at higher pressure, the study of adsorption isotherm is required. Langmuir, Freundlich, Dubinin-Radushkevich and Temkin isotherm models were applied to poly[VBTMA][Arg] at temperature 298 K, 313 K and 333 K. Figure 4.22 shows the isotherm graphs. All the parameters evaluated by linear regression. The correlation coefficient (R^2) was also used to determine the best fitting isotherm to the experimental data.

Figure 4.22: Adsorption isotherms a) Freundlich b) Langmuir c) Dabunin-Radushkevich and d) Temkin isotherm by linear regression method for poly[VBTMA][Arg] at 298 K, 313 K and 333 K.

Figure 4.22 shows the CO₂ sorption at different temperature, 298 K, 313 K and 333 K. From the isotherms graph shows that when temperature increases, the CO₂ sorption capacity decreases due to the reduction in binding strength between the CO₂

and poly[VBTMA][Arg] [164]. The reduction of CO₂ capacity shows that the sorption is exothermic thus showed that the involvement of physical adsorption process [165]. In physical adsorption, higher surface adsorption energy and molecular diffusion at elevated temperatures results instability of the CO₂ on AAPILs surface thereby promotes the desorption process at higher temperature. The increment of temperature accelerates the internal energy of the adsorbent, hence releases the CO₂ molecules from the surface [166]. The predicted isotherm constants for the CO₂ sorption and the corresponding R^2 value from the linear regression method are shown in Table 4.12.

Table 4.12: Adsorption isotherm parameters at 298 K, 313 K and 333 K

Freundlich				Langmuir			
Type	298 K	313 K	333 K	Type	298 K	313 K	333 K
K_F	3.582	1.964	0.99	q_m	8.258	4.943	7.547
n	3.09	2.966	1.605	K_L	0.6229	0.507	0.122
$1/n$	0.32	0.34	0.62	R_L	0.69	0.73	0.918
R^2	0.9837	0.9575	0.8858	R^2	0.9632	0.9514	0.5059
Dubinin Radushkevich				Temkin			
q_m	6.07	3.38	2.70	B	1.5635	0.9369	0.9158
λ	1.38×10^{-7}	1.25×10^{-7}	1.98×10^{-7}	K_T	9.816	7.859	2.718
E	1.9	2.003	1.588	b_T	1585	2778	3023
R^2	0.8225	0.7026	0.5993	R^2	0.941	0.9042	0.8288

Based on Table 4.12, the Langmuir constant, K_L and Freundlich constant, K_F that relates with the adsorption affinity are decreases at higher temperature. This is

because the bond strength between CO₂ and poly[VBTMA][Arg] decreased with increasing temperature thus indicate exothermic process. Le Chatelier's principle explain that desorption is favorable at elevated temperatures and caused the reduction of CO₂ sorption due to endothermic process. The maximum CO₂ capacity (q_m) is 8.258 mmol/g at 298 K and reduced at higher temperature. The essential characteristics of Langmuir equation is expressed as a dimensionless separation factor (R_L).

$$R_L = \frac{1}{1 + K_L P_o} \quad 4.4$$

The value of R_L indicates the isotherm shape to be unfavorable ($R_L > 1$), favorable ($0 < R_L < 1$) and irreversible $R_L = 1$. Based on Table 4.11 the R_L values which is within the range of 0-1 suggests that the CO₂ sorption is favorable even at higher temperature [127]. The favorability of the CO₂ sorption can be supports by Freundlich isotherm.

The favourable adsorption in Freundlich isotherm is when the Freundlich constant, n , has the range of 1 to 10 [167]. From Table 4.11 can be seen that the n values are within this range thus supports the favorable sorption from Langmuir. The constant K_F is an approximate indicator of adsorption capacity, and can be seen that the K_F values decreases with increasing temperature which indicates the reduction of CO₂ capacity. The strength of adsorption process can be explain by $1/n$ where $1/n > 1$ is an indicative of cooperative adsorption [127] whereas $1/n < 1$, indicates a normal adsorption as shows in Table 4.12.

Dubinin Radushkevich and Temkin isotherms provide a useful information related to the energy data estimation, in terms of mean free energy of adsorption (E), sorption energy value (B) and heat of adsorption (b_T) [168]. In Dubinin Radushkevich isotherm, it is used to determine the apparent energy of CO₂ sorption to poly[VBTMA][Arg]. The calculated E values which are within the range of 1-2 kJ/mol suggests that the CO₂ sorption is physical in nature as the magnitude of E is below 8 kJ/mol which indicate the chemisorption process [169]. The high values of q_m shows high sorption capacity at lower temperature and decreases with temperature increased. The value of the apparent energy of adsorption, also depict the physisorption process. From here can be said that the physisorption is dominant instead of chemisorption when pressure increases.

The Temkin isotherm is usually for the heterogeneous surface energy systems (non uniform distribution of sorption heat). Where B is constant related for heat of sorption (J/mol) and can be calculated from:

$$B = \frac{RT}{b_T} \quad 4.5$$

It decreased with increasing temperature from 1.5635 J/mol to 0.9158 J/mol indicating that the heat of adsorption of CO₂ to AAPILs decreases with increasing temperature from 298 K to 333 K, thus it is an exothermic. Besides the E validation test, sorption energy value (B) and heat of adsorption (b_T) values were lower than 20 kJ/mol thus shows a characteristic in physical adsorption [132]. This is also called non specific adsorption which occur as a result of long range weak van der Waals forces between adsorbate and adsorbent [168].

On the basis of R^2 value, the Freundlich model gives the best fit towards the experimental data over the entire temperature range. Therefore, it implies that the surface of poly[VBTMA][Arg] is heterogenous and a multi layer CO₂ sorption occurs and does not restrict to monolayer as proposed in Langmuir type. This multilayer also confirmed the BET model as reported earlier at higher pressure. This Freundlich isotherms primarily represents the physisorption process since it allows these CO₂ molecules to form a successive layer onto the surface of AAPILs. However, Dubinin Radushkevich isotherm is found to be the poorest fit of all experimental data.

4.9 Thermodynamic analysis

The thermodynamic parameters for the CO₂ sorption were estimated by van Hoff's formulation [132, 133, 169]. The change in Gibbs free energy (ΔG°), change in enthalpy of reaction (ΔH°) and change in entropy of adsorbent and adsorbate interaction (ΔS°) can be estimated by following the equation 4.6 and equation 4.7.

$$\ln K_F = \Delta S/R - \Delta H/RT \quad 4.6$$

$$\Delta G = -RT \ln K_F \quad 4.7$$

Adsorption constant is the equilibrium constant, K_{eq} , therefore, they obey the van Hoff's formulation [127]. A plot of $\ln K_F$ versus $1/T$ as shown in Figure 4.23 was used to determine the ΔH° and ΔS° of adsorption by following Equation 4.8.

$$\ln K_F = \frac{\Delta S}{R} - \frac{\Delta H}{RT} \quad 4.8$$

Based on Equation 4.6 to 4.8, R represents the universal gas constant (8.314 J/mol.K), T is adsorption temperature in K and K_F is the Freundlich constant deduced from the Freundlich isotherm fit [169].

Figure 4.23: Thermodynamic parameters by using van Hoff's equation

The estimated values of thermodynamic parameters are tabulated in Table 4.13. The experimental data show the capacity of CO₂ sorption decreased with increasing temperature. This indicates that the negative sign of ΔH° value indicates an exothermic nature of the CO₂ sorption process. In addition, for an exothermic reaction, the van Hoff's plot should always have a positive slope. The ΔS° can be interpreted by the behavior of the CO₂ molecules upon the adsorption process, which is from randomized to an ordered form on the surface of the adsorbent. The negative value of ΔS° suggests high orderliness of the adsorbate molecules upon adsorption.

The negative value of ΔG° indicates the spontaneous nature of CO₂ sorption by poly[VBTMA][Arg] [133, 169-171].

Table 4.13: Thermodynamics parameters of CO₂ adsorption

Sample	ΔH° (kJ/mol)	ΔS° (kJ/mol.K)	ΔG° (kJ/mol)			Ref.
			298 K	313 K	333 K	
Poly[VBTMA][Arg]	-30.3	-91.14	-3.16	-1.76	0.27	Present work
[C ₄ mim][CF ₃ CF ₂ CF ₂ CF ₂ SO ₃]	-11.9	-40.0	n/a	n/a	n/a	[172]
[C ₂ CNDim][DOSS]	-12.9	-61.65	4.94	n/a	n/a	[158]
[P ₆₆₆₁₄][Meth]	-64	n/a	n/a	n/a	n/a	[68]

The magnitude of ΔH° denotes the type of CO₂ absorption process either physical or chemical sorption. The enthalpy (ΔH°) from experimental data is -30.3 kJ/mol which is intermediate from physical sorption (-10 to -20 kJ/mol) and chemical sorption with conventional amine (-80 to -100 kJ/mol) [173]. The calculated ΔH° which is > -20 kJ/mol suggests that both of physisorption and chemisorption involved in the reaction. In addition, larger the negative value for enthalpy indicates stronger IL/CO₂ interaction. By comparing the experimental ΔH° (-30 kJ/mol) with ΔH° for [P₆₆₆₁₄][Meth] [68], it can be seen that the enthalpy for poly[VBTMA][Arg] is lesser. The smaller change in enthalpy on AAPILs compared to the reported AAILs [68], indicates that less energy is required for the regeneration of AAPILs, and therefore by polymerizing the AAILs can potentially impact positively on the energy balance on the recovery process.

The ΔG° values are divided into two regions which is at low temperature (25 and 40 °C) with a negative value and high temperature (60 °C) with a positive value. The

increase of ΔG^o with increasing T indicates that the CO₂ sorption consumes more energy with increasing temperature. The negative of ΔG^o confirms the feasibility of the process and indicates an occurrence of the favorable and spontaneous adsorption [166] whilst positive value at an elevated temperature implies a non-spontaneous adsorption reaction [165]. In addition, decreased in negative ΔG^o value with increasing temperature implies that the CO₂ sorption process is more favorable at 298 K rather than 333 K. For the special condition where $\Delta G^o = 0$, the reaction is at equilibrium at standard conditions, with $K_F = 1$. According to Table 4.12, the K_F value is 0.99 at 333 K, thus give ΔG^o with 0.27 kJ/mol. Therefore, ΔG^o is at equilibrium when temperature is almost 333 K. The negative value from the entropy ΔS^o , can be explain by the structuring effect caused by the specific interactions between the solute and the charge centers of the ILs [158].

4.10 Kinetic Studies on poly[VBTMA][Arg] at different temperature

The prediction of kinetics is necessary for the design of adsorption systems. The kinetic parameters which is helpful for the prediction of adsorption rate, gives important information for designing and modeling the processes [174]. Successful application of the adsorption demands innovation of cheap, easily available and abundant adsorbents of known kinetic parameters and sorption characteristic [175].

The kinetics studies of CO₂ adsorption into the poly[VBTMA][Arg] was studied by using various kinetic models such as pseudo-first order, pseudo second order, Elovich and intra particle model. In addition, the reliability of these kinetic models in predicting the adsorption capacity is accessed by linear regression coefficient, R^2 and relative error (ε) which is defined in Equation 4.9;

$$\varepsilon \% = \frac{q_{e,calc} - q_{e,act}}{q_{e,act}} \times 100\% \quad 4.9$$

Based on Equation 4.9, $q_{e,cal}$ is refers to the measured value that is obtained from the kinetic analysis, whilst $q_{e,act}$ is the actual value of the adsorption capacity based on the experimental work [165].

4.10.1 Pseudo-first order kinetic model

The earliest work that has been reported on kinetic study was conducted by Lagergren in 1898 is given as;

$$\frac{dq_T}{dt} = k_1(q_e - q_t) \quad 4.10$$

$$\log(q_e - q_t) = \log q_e - \left(\frac{k_1}{2.303}\right).t \quad 4.11$$

Where q_t and q_e are the adsorption capacity at any particular time and at equilibrium respectively and k_1 is the pseudo first order constant with unit of 1/min. By integrating the equation results in a linearized form as Equation 4.11, hence plotting graph of $\log (q_e - q_t)$ versus time yields a linear function in which $\log (q_e)$ and $(k_1/2.303)$ is the y-intercept and slope, respectively as shown in Figure 4.24 [176]. Based on Figure 4.24 and Table 4.14, it was shown that pseudo first order fits the CO₂ sorption at all temperature with the regression coefficient values mostly greater than 0.98 and the relative error is lower, ε compared to pseudo second order model. The adsorption capacities from the experimental data and predicted by the pseudo first order has a good agreement with each other. This is because the first order of adsorption process suggests the faster diffusion of CO₂ molecules into the adsorbent surface [177]. Pseudo first order rate constant, K_1 was the highest at 333 K with 0.03155 min⁻¹ suggesting the fastest adsorption kinetics among other temperatures [178]. Although the reaction rate becomes faster at a higher temperature, less CO₂ being adsorbed due to the faster desorption of CO₂ [179].

Figure 4.24: Kinetic plot of pseudo first order model at various temperatures.

Table 4.14: Kinetic parameter of Pseudo first order

Kinetic model	Parameter	Temperature (K)		
		298	313	333
	$q_{e, act} (mmol/g)$	7.9099	4.1358	3.7814
Pseudo first order	$K_I (1/min)$	0.0232	0.02695	0.03155
	$q_{e, cal} (mmol/g)$	6.56	4.598	4.332
	R^2	0.9943	0.9876	0.9922
	Relative error, ε (%)	16.99	11.18	14.56

4.10.2 Pseudo second order kinetic model

Pseudo second order reaction also often cited in literature [180, 181]. The equation of pseudo second order is represented as below:

$$\frac{t}{q_t} = \frac{1}{k_2 \cdot q_e^2} + \frac{t}{q_e} \quad 4.12$$

$$h = k_2 \cdot q_e^2 \quad 4.13$$

Where k_2 is the pseudo second order rate constant, t is the contact time of gas-solid in min, while q_e and q_t is the adsorption capacity at equilibrium and particular time t , respectively and h is corresponds to the initial adsorption rate (mmol/g min).

Figure 4.25: Kinetic plot of pseudo second order model at various temperatures.

Table 4.15: Kinetic parameter of Pseudo second order

Kinetic model	Parameter	Temperature (K)		
		298	313	333
	$q_{e,act}$ (mmol/g)	7.9099	4.1358	3.7814
Pseudo second order	$q_{e,cal}$ (mmol/g)	8.9286	-2.68	1.666
	K_2 (g/mmol min)	4.58×10^{-3}	4.197×10^{-3}	9.436×10^{-3}
	h (mmol/g min)	0.3651	0.03014	0.0262
	R^2	0.993	0.2448	0.2518
	Relative error, ε (%)	11.41	164.8	55.94

From Figure 4.25 can be seen that the model poorly fit into the kinetic data. Due to its low value of R^2 value (range of 0.22 to 0.99) and large relative error as depicted in Table 4.15. This higher percentage (%) error indicates that this model is not able to describe the adsorption process of CO₂ on poly[VBtMA][Arg]. The initial

adsorption rate (h) that decreases with temperature verified the physisorption and exothermic behaviour during the adsorption at high pressure. From Table 4.15, the initial adsorption rate (α) decreases with an increase in temperature from 0.8193 to 0.2316 for 298 K and 333 K respectively. This is due to the higher kinetic energy of the CO₂ at a higher temperature in which the tendency of CO₂ to escape from the adsorbent also increased.

4.10.3 Elovich kinetic model

In addition with the pseudo first order and second order model, Elovich kinetic model is frequently applied in gas – solid reaction, and is expressed as follows:

$$\frac{dq_t}{dt} = \alpha \exp(-\beta q_t) \quad 4.14$$

Where α is the initial adsorption rate (mg/g min), while β is the extent of surface coverage and activation energy of the process. The boundary conditions in which $\alpha\beta$ is assumed ≥ 1 , $q_t = 0$ at $t=0$ and $q_t = q_t$ at $t=t$ is being applied in equation, and upon integration, it results in new equation as shown in Equation 4.15.

$$q_t = \frac{1}{\beta} \ln(\alpha\beta) + \frac{1}{\beta} \ln t \quad 4.15$$

Based on Equation 4.15, if the CO₂ sorption fits the Elovich model, the Elovich plots of q_t versus $\ln(t)$ will yield a straight line with slope of $1/\beta$ and y intercept of $1/\beta \ln(\alpha\beta)$. Based on Table 4.16, the initial adsorption rate (α) decreased with temperature from 0.8193 to 0.2316 for 298 K and 333 K respectively. This is similar to that of initial adsorption rate (h) from pseudo second order model. The Elovich model also describes the desorption process that is taking place as well as the value of β is equivalent to desorption rate [165].

As can be seen from Table 4.16, the magnitude of β which increased from 0.5217 g/mmol at 298 K to 0.8364 g/mmol at 333 K indicates that desorption was dominant at higher temperature. As shown in Figure 4.26, Elovich kinetic model does not fitted well into the experimental data with the regression coefficient within 0.96 to 0.99.

Figure 4.26: Elovich plot of CO₂ sorption at various temperatures

Table 4.16: Kinetic parameters of Elovich isotherm

Kinetic model	Parameter	Temperature (K)		
		298	313	333
	$q_{e, act} (mmol/g)$	7.9099	4.1358	3.7814
Elovich	$\beta (mmol/g)$	0.5217	0.7679	0.8364
	$\alpha (mmol/g \text{ min})$	0.8193	0.2299	0.2316
	R^2	0.9921	0.9639	0.9675

4.10.4 Intra-particle diffusion kinetic model

Intraparticle diffusion model provides the diffusion mechanism of the adsorption process. This model is defined by Equation 4.16.

$$q_t = kt^{\frac{1}{2}} + C \quad 4.16$$

Where q_t is the amount adsorbed at any particular time (mmol/g), k is the intraparticle diffusion rate constant (mmol/g min^{1/2}) and C (mmol/g) relates to the thickness of boundary layer. If the adsorption process obeys the intra-particle diffusion model, a straight line plot against half power of time, $t^{1/2}$ passes through the

origin is expected, with slope of k and y intercept of C . In any adsorption process, there are multiple steps that occurs such as mass transfer of adsorbate to adsorbent surface (bulk diffusion), film diffusion (external mass transfer resistance) and followed by surface diffusion into the internal sites (intra-particle diffusion) [165, 176].

Figure 4.27: Intra-particle diffusion model at different temperatures

Table 4.17: Kinetic parameters of CO₂ sorption onto poly[VBTMA][Arg]

Kinetic model	Parameter	Temperature (K)		
		298	313	333
	$q_{e, act} \text{ (mmol/g)}$	7.9099	4.1358	3.7814
Intra-particle diffusion model	$K \text{ (mmol/g min}^{1/2}\text{)}$	0.7445	0.5899	0.5766
	$C \text{ (mmol/g)}$	0.3669	-1.2317	-1.1473
	R^2	0.9674	0.9782	0.99

Figure 4.27 shows the intraparticle diffusion plot for different reaction temperatures applied in this study and the corresponding kinetic parameters were tabulated in Table 4.17. From the Figure 4.27 can be seen that the kinetic parameter

plot does not fit well into the kinetic model. Kinetic parameters at different temperature and its corresponding coefficient were summarized in Table 4.17.

4.11 Evaluation of activation energy

Ease of adsorption process requires the minimum activation energy. Activation energy can be calculated by using the Arrhenius equation as shown in Equation 4.17.

$$\ln k_1 = \ln k_0 - \frac{E_a}{RT} \quad 4.17$$

According to Equation 4.17, k_1 is pseudo first order constant, k_0 is the temperature impact factor, E_a is the apparent activation energy for adsorption (J/mol), R is the gas constant (8.314 J/mol K) and T is the adsorption temperature in K. By plotting $\ln k_1$ versus the reciprocal of temperature yields a straight line with y-intercept of $\ln k_0$ and slope of $(-E_a/R)$ as shown in Figure 4.28.

Figure 4.28: Fitting of Arrhenius equation

The activation energy of this present study was found to be approximately 7.23 kJ/mol and k_0 is 0.43145. This E_a is typically low compared with the adsorption of CO₂ by using activated carbon with 17 kJ/mol [165]. The value of activation energy is low due to weak interaction forces between adsorbent and adsorbate at high pressure [165]. Thus, the lower value of the activation energy shows that the CO₂

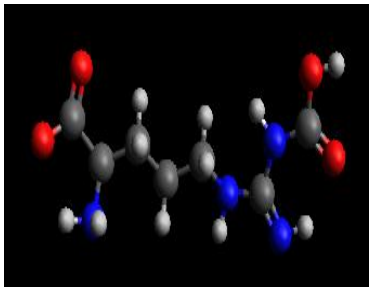

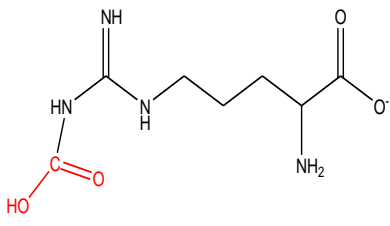

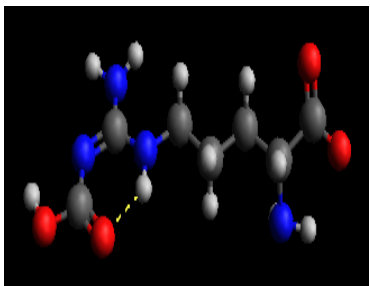

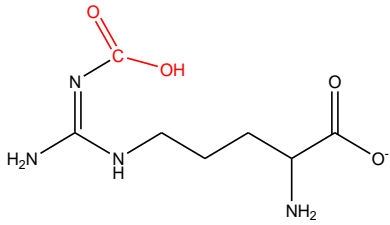

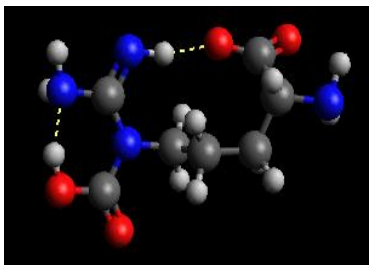

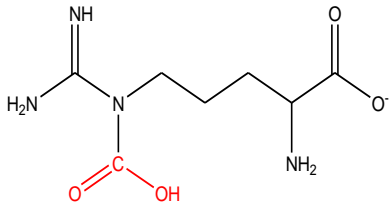

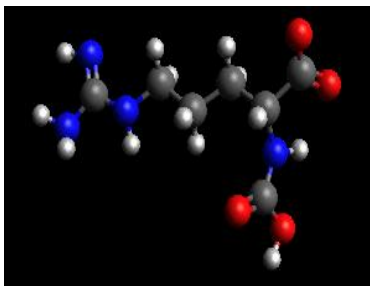

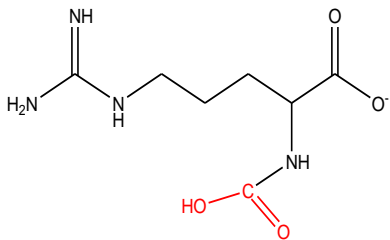

sorption investigated falls under physisorption at these temperatures and 10 bar pressure.

4.12 Density Functional Theory (DFT) on Thermochemistry Calculation

The energy and electronic structure of the molecular systems were computed with Density Functional Theory (DFT) calculations using *Gaussian 09* with the *B3LYP* functional and *6-31G** basis set. The reaction energy of amine and CO₂ can be studied to understand the role of amine-CO₂ reaction energy by systematically different amines. In arginate structure with given multiple numbers of amines presence, it is important to understand the connection between the amine molecular structure and its reaction energy with CO₂.

The molecular modeling within the framework of DFT was carried out by co-worker. It was used to evaluate the reaction energy to form the product species associated with the amine-CO₂ system [182]. This DFT was used to relate electronic structure properties of the amines in their reactivity and to design the target amine with reactivity towards CO₂. The energies are likely to be affected by the ILs media. By following the method reported by Saravanamurugan *et al.* [105], that a solvent and the cation were not included in the calculations since the solvent-property and the diffraction data for the studied ILs structures were not available. Therefore, without inclusion of such experimental data (*i.e.*, cations with specific conformations) the model would most likely to be improved [105]. Table 4.18 below shows the molecular structure of different conformations of arginate with CO₂ and the electronic energy and enthalpy for each conformation.

Table 4.18: Molecular structures and enthalpy reaction of arginine and CO₂

Molecular structure (3D)	Molecular structure (1D)	electronic energy + enthalpy (kcal/mol)	ΔH (kJ/mol)
1 mol CO₂ + 1 mol arginine			
		-498431.15	-30.42
		-498440.01	-32.61
		-498453.90	-89.75
		-498443.21	-59.14

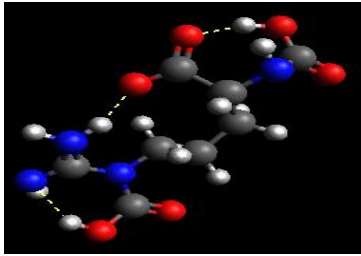

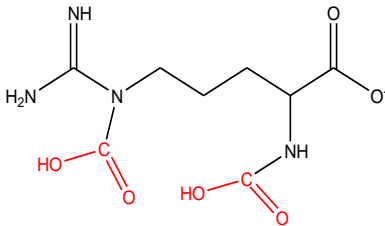

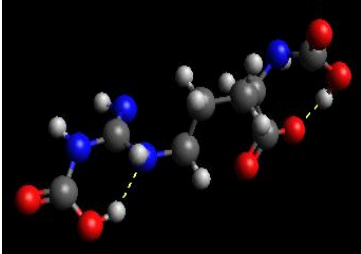

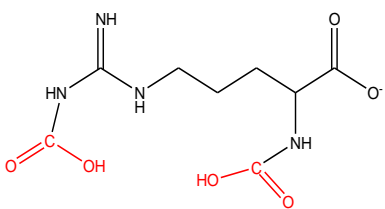

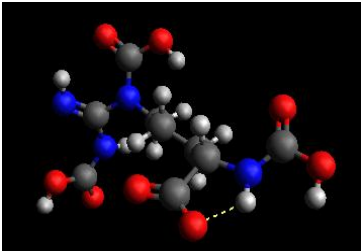

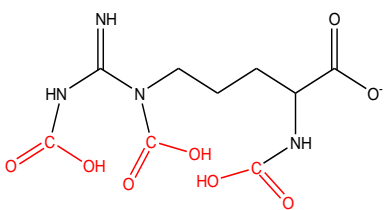

2 mole CO₂ + 1 mole arginate			
		-616771.49	-110.27
		-616762.29	-92.68
3 mol CO₂ + 1 mol arginate			
		-735077.49	-14.30

Table 4.18 shows the electronic molecular structure and electronic enthalpy and enthalpy reaction for the arginate complex with CO₂. Since in arginate structure has two primary and two secondary amines functional, there are various composition where 1 mol of CO₂ could be attached to 1 mol of arginate. The enthalpy reaction for 1 mol of CO₂ reacts with 1 mol of arginate is from -30 kJ/mol to -90 kJ/mol. When 2 mol of CO₂ attached with 1 mol of arginate, the enthalpy higher from -92 kJ/mol to -110 kJ/mol showing that strong chemical bonding between CO₂ and amine, hence more CO₂ could be absorb. However, when 3 mol of CO₂ attached with 1 mole of arginate, the enthalpy of reaction drop to -14.30 kJ/mol. This might be caused by the steric repulsion dominated when CO₂ crowded in arginate. In our experiment, the enthalpy of reaction is -30.3 kJ/mol. This result has a good agreement with enthalpy calculated by DFT with -30.42 kJ/mol when 1 mol of CO₂ reacts with 1 mol arginate. Thus, the mechanism 1:1 is achieved. The CO₂ sorption

capacities in [VBTMA][Arg] with 0.83 mol/mol and poly[VBTMA][Arg] with 1.14 mol/mol proved the mechanism 1:1.

4.13 Proposed Mechanism of poly[VBTMA][Arg] with CO₂

The mechanism of CO₂ with TSILs proposed by Bates *et al.* [67] stated when the amine is attached to the cation, the carbamate formation is favoured. However when the amine bound to the anion, the formation of carbamic acid is the favoured one [68].

By using amino acid as anions, many researchers [68, 70, 96] have proposed a new mechanism with the formation of carbamic acid. It was shown that 1 mol ILs can absorb 1 mol of CO₂ (1:1 mechanism). The proposed mechanism as in literature reported for AAILs with CO₂ is shown in Figure 4.29.

Figure 4.29: Proposed mechanism of AAILs with CO₂ [68]

In Figure 4.29, when amino acid anion reacts with CO₂, carbamic acid was formed as shown in first formation (1). When this carbamic acid react with any base, or in non aqueous medium (amino acid itself act as base), dianion are formed as shown in second (2) formations. This is supported by Gurkan *et al.* [68] that the reaction between AAILs and CO₂ terminates at formation of carbamic acid (1) without forming a carbamate species (2). The dianion formed in the second formation (2) is chemically unstable therefore the reaction would expect to terminate

at first formation upon addition of CO_2 to AAPILs. This indicates a potential absorption stoichiometry of 1:1 (CO_2 : IL).

Therefore, the maximum capacity can be achieved is 1 mol/mol. However, for polymerized AAPILs, the CO_2 sorption capacities can be more than 1 mol/mol due to involvement of physical adsorption [105]. Figure 4.30 below shows the proposed mechanism of AAPILs which is poly[VBTMA][Arg] with CO_2 .

Figure 4.30: Proposed mechanism of poly[VBTMA][Arg] with CO_2

Figure 4.30 shows the proposed mechanism of one mol of CO_2 react with one mol of arginate and formed carbamic acid. Initially, the addition of CO_2 to nitrogen in amine functionalized in arginate would form a carbamate bond with the formation of zwiterion. The reaction proceeds with the proton shifting from the amine onto the newly bound of CO_2 thus form a carbamic acid.

In the simple route, the chemisorptions of CO_2 to the amine group is an elemental reaction where the proton migrates from the amine to an oxygen atom of the

incoming CO₂ molecules [105]. From DFT calculation, only one primary amine react with one mole of CO₂ as shown in Figure 4.30 giving ΔH° is -30.42 kJ/mol. This theoretical ΔH° is similar with experimental ΔH° which is -30.3 kJ/mol. Therefore, the proposed mechanism followed the 1:1 mechanism where 1 mol CO₂ reacts with 1 mol arginate, which only 1 amine reacted with CO₂ at ambient pressure. However, in higher pressure, the possibility of CO₂ to react with one or more amines is higher since arginate comprises of two primary and two secondary amine sites. Therefore, more CO₂ capacities can be achieved in high pressure.

4.14 Characterization of AAPILs after CO₂ sorption

The characterization of AAPILs after CO₂ absorption can be characterized by using FTIR before and after CO₂ absorption. FTIR before and after CO₂ absorption of poly[VBTMA][Arg] are shown in Figure 4.31. All of FTIR spectrum can be found in Appendix B.

Figure 4.31: FTIR before and after CO₂ sorption of poly[VBTMA][Arg]

Figure 4.31 shows a FTIR spectrum of poly[VBTMA][Arg] before and after CO₂ sorption to see any peak changes and Figure 4.32 shows a carbamic formed at arginate.

Figure 4.32: Carbamic acid formed at argininate

For poly[VBTMA][Arg], the reaction CO_2 and amine shows a broad peak in range $3346 - 3188 \text{ cm}^{-1}$ corresponds to $-\text{NH}$ in secondary amides and OH overlapped in carbamic acid formed. A peak with high intensity at 1639 cm^{-1} corresponds to the $\text{C}=\text{O}$ and the peaks at 1560 cm^{-1} and 1476 cm^{-1} corresponds to $-\text{NH}$ in secondary amides that were formed in carbamic acid species as shown in Figure 4.32. The reaction of CO_2 and NH_2 was confirmed in poly[VBTMA][Arg].

For poly[VBTMA][Lys], poly[VBTEA][Lys], poly[VBTBA][Lys], poly[VBMI][Lys] and poly[VBPPN][Lys], the intensity for all peaks increased after CO_2 absorption. Peak at 3344 cm^{-1} increased and became broader, which corresponds to $-\text{NH}$ in secondary and overlapped with $-\text{OH}$. The increasing peak intensity at 1581 cm^{-1} indicated the $-\text{C}=\text{O}$ overlaps with the $-\text{NH}$ after formation of carbamic acid species.

For poly[VBTMA][Hist], high intensity for all peaks are observed after CO_2 absorption and new peak is observed at 1631 cm^{-1} , indicating the formation of carbamic acid species. The broad peak and high intensity are observed in range 3200 to 3350 cm^{-1} indicating the $-\text{NH}$ secondary peak after reaction with CO_2 . For poly[VBTMA][Tau], the increased of intensity for all peaks can be observed after CO_2 absorption, especially in range of 3200 to 3350 cm^{-1} for the $-\text{NH}$ peaks. The new peak is observed at 1641 cm^{-1} indicating the formation of carbamic acid.

In poly[VBTMA][Pro], the new peak is also observed at 1643 cm^{-1} after CO_2 absorption showing the formation of carbamic acid. For poly[VBTMA][Ser], the increasing of intensity for all peaks can be observed especially in the range 3200 to 3400 cm^{-1} showing broad peaks of $-\text{NH}$ secondary. Peak at 1571 cm^{-1} indicating the carbamic acid species been overlapped with $-\text{C}=\text{O}$ from carbonyl salts. In poly[VBTMA][Ala] and poly[VBTMA][Gly], increasing intensity is observed after CO_2 absorption especially in $-\text{NH}$ region and $-\text{C}=\text{O}$ region.

From all the FTIR spectrums it can be shown that after CO₂ absorption, some of the samples clearly show the formation of carbamic acid species *i.e.* poly[VBTMA][Arg], poly[VBTMA][Hist], poly[VBTMA][Tau] and poly[VBTMA][Pro]. But for other AAPILs like poly[VBTMA][Lys], poly[VBTEA][Lys], poly[VBTBA][Lys], poly[VBMI][Lys], poly[VBPPN][Lys], poly[VBTMA][Ser], poly[VBTMA][Ala] and poly[VBTMA][Gly], it showed the overlapping of carbamic acid species with –COO⁻ from carbonyl salts. Generally, it was observed the increasing of intensity for all samples after CO₂ been absorbed. This showed those both chemical and physical adsorptions are involved in AAPILs after reaction with CO₂.

4.15 Effect of water to AAPILs

A study on effect of water to AAPILs for CO₂ capture is needed since in natural gas contains impurities of moisture. The solubility measurement was made by using dry ice method as follows the method by Vijayraghavan *et al.* [88]. The CO₂ sorption of ILs is substantially sensitive to their water content [89, 183-185]. The presence of water can even produce chemical instability of the ILs [186-188]. However, there are cases where the presence of water improves the level of absorption [17, 97].

Figure 4.33 shows the effect of water with additional of 2 mol and 4 mol of water to AAPILs (poly[VBTMA][Gly], poly[VBTMA][Ala], poly[VBTMA][Ser] and poly[VBTMA][Pro]). A huge increment in sorption capacity of AAPILs was achieved with addition of water. It can be seen that with additional 4 mole of water the CO₂ sorption increased up to 12 w/w% for poly[VBTMA][Gly].

Figure 4.33: Effect of water to AAPILs

Hu *et al.* [118] have studied the effect of water to the sorption of CO₂ capacity. The results indicate that presence of water promotes the absorption of CO₂. The absorption capacity increases from 0.96 mol/mol to 1.91 mol/mol when water content increases from 0 % to 30 %. Therefore shown that water content of ILs has direct effect on their CO₂ sorption capacity [118].

Water promotes ionization of the ILs. This suggests that the water makes the ILs generate more H⁺ and any other ions after absorbing with CO₂ [43]. The hydration reaction occurred between water and CO₂ formed carbonic acid as shown in 4.18 [118].

A reaction as shown in equation 4.19 is a proton transfer from carbonic acid to amino acid anion. Since CO₂ is a weaker acid than amino acid, the proton transfer would not supply enough thermodynamic driving force for chemisorption. Therefore any hydrogen bond acceptors present in CO₂ loaded absorbents such as amino acid and bicarbonate anion are candidates for hydrogen bond partners for amino acid as

shown in 4.22 [189]. The amino acid anions also may react with amino acid that formed in reaction 4.19 to form hydrogen bond.

Hence, more reaction capability between CO_2 , H_2O and amino acid anion are formed. Thus, the CO_2 sorption capacity also increases. In view, these stoichiometry of chemisorption is most reasonably represented by the following equation [189]:

With the addition water, the hydration reaction between water in ILs and CO_2 makes the absorption capacity higher compared to dry ILs [118]. The significant increment of CO_2 sorption can be explained by swelling behavior. Since the AAPILs are in solid form, the water content plays a major role in increasing the surface area due to swelling behaviour. This will offer a great surface area for CO_2 to be hosted. Secondly, the water itself consists of H^+ and OH^- anion and they may act as standalone cation and anion enhancing the CO_2 sorption [3]. Therefore, these AAPILs can be considered as highly feasible for industrial application.

4.16 Comparison of gas solubility in poly[VBTMA][Lys]

Natural gas contains a large number of impurities and selectivities like CO_2/CH_4 , CO_2/SO_x , $\text{CO}_2/\text{H}_2\text{S}$ which might also become important. Besides CO_2 , methane (CH_4) is largely contained in natural gas with 40-50 % and nitrogen (N_2) with 0-5 %. Thus, reliable knowledge on their solubility in ILs is needed for developing process models.

Separation processes involve mixtures of two or more components are important hence solubility data only is not enough for the performance of AAPILs. Nevertheless, for CO_2 capture from natural gas, the CO_2/CH_4 and CO_2/N_2 is mainly relevant. The solubility measurements were made using a single gas of CO_2 , CH_4 and

N₂. Figure 4.34 shows the comparison of gas solubility on poly[VBTMA][Lys] with CO₂, CH₄ and N₂ gases at 1 bar, 303 K.

Figure 4.34: Comparison of gases on poly[VBTMA][Lys] at 1 bar, 303 K

From Figure 4.34 can be seen that the sorption of CO₂ gas is higher as compared to N₂ and CH₄ gases. CH₄ sorption has much lower solubility than CO₂ but higher than N₂. Since the sorption of gases in AAPILs is governed by the interaction between the gas molecules and polymer molecules, it is worth to look at these gases polarizabilities. Table 4.19 shows the values of polarizabilities and gas sorption for each gas.

Table 4.19: Polarizabilities (α) and gas sorption of each gas

Gas	$\alpha \times 10^{24}$, [cm ³]	Gas sorption (wt%)
Carbon dioxide, CO ₂	2.64	12.9
CH ₄	2.6	1.3
Nitrogen, N ₂	1.74	0.8

The most important property that determines these interactions is the polarizabilities, α [190]. The capabilities AAPILs to capture CO₂ is higher with 12 wt% followed with CH₄ (1.3 wt%) and N₂ (0.8 wt%). This trend correlates well with

their polarizabilities as shown in Table 4.19. It is seen that these energies are nearly proportional to α thus contribute on higher sorption.

The molar selectivities toward CO₂ was calculated based on the single gas absorption measurements for CO₂ and N₂ as expressed in below Equation 4.25.

$$S_{CO_2/N_2} = \frac{\left(\frac{wt\ CO_2}{wt\ ILS}\right)}{\left(\frac{wt\ N_2}{wt\ ILS}\right)} = \left[\frac{wt\ CO_2}{wt\ N_2}\right] \quad 4.25$$

The selectivities of S_{CO_2/N_2} calculated is 9.92 and selectivities of S_{CO_2/CH_4} is 16.13. This is showed that the selectivity of CO₂ from CO₂+CH₄ is higher than N₂+CO₂.

CHAPTER 5

CONCLUSIONS AND RECOMENDATIONS

5.1 Conclusions

Eight anions have been used to synthesize the AAPILs *i.e.* [Arg], [Lys], [Hist], [Tau], [Pro], [Ser], [Ala] and [Gly] with ammonium based, [VBTMA], as cation. The studied shows that [Arg] and [Lys] which have greater numbers of amines in the structure have higher CO₂ absorption than other anions because of greater chance of amines to react with CO₂. COSMO-RS also was carried out to study the chemical potential on activity coefficient of CO₂ towards the ILs. The trends of activity coefficients are similar with experimental results and the interaction between anions and CO₂ also are explained further by σ -profile and σ -potential. By polymerizing the monomers, AAPILs, the CO₂ absorption increased to almost double from the monomeric forms.

To study the effects of different cation, ammonium based [VBTMA] gave higher CO₂ sorption and [VBMI] gave the least sorption. By changing the alkyl chain length in cation, methyl, [VBTMA], gives the highest CO₂ sorption. The CO₂ sorption decreases with longer alkyl chain as it may hinder the interaction between CO₂ and the cation due to steric effects.

The FTIR results after CO₂ absorption shows the formation of carbamic acid species which confirms the chemical absorption. When pressure increase, the CO₂ sorption increased due to the physical adsorption. At low pressure, a large uptake of CO₂ can be expected to be due to the chemical absorption process and the further increase at higher pressure is in part of physical adsorption. BET isotherm model shows type II which attributed to the multilayer formation of CO₂ on AAPILs thus explained the increasing of CO₂ adsorption at higher pressure.

By increasing the temperature to 80 °C, almost fully desorption occurred. The recyclability of AAPILs been studied where the pressure and temperature swing applied. The result shows that AAPILs are very stable and can be use up until 86 % sorption in 5th cycle to get approximately 1 mol CO₂ captured per mole of monomer. This shows that these AAPILs can be reuse more than 5 times.

The adsorption isotherm follows Freundlich isotherm and thermodynamic analysis gives the ΔH° is -30.3 kJ/mol. The kinetics studies of CO₂ sorption showed that the CO₂ sorption follows pseudo first order by using the best fitted in correlation coefficient (R^2).

DFT calculation showed that the mechanism of 1:1 is achieved when one mol of CO₂ react with one mole of arginate with ΔH° is -30.42 kJ/mol. This is similar with change of enthalpy in experimental with -30.3 kJ/mol. Therefore, the mechanism between CO₂ and arginate can be proposed with formation of carbamic acid.

With the addition water, the hydration reaction between water in ILs and CO₂ makes the absorption capacity higher compared to dry ILs. In hydration reaction, the reaction between CO₂ and H₂O formed the carbonic acid where this carbonic acid may form a hydrogen bond with amino acids anion. The addition of water also plays a major role in increasing the surface area due to swelling behavior since AAPILs are in solid form. This will offer a great surface area for CO₂ to be hosted. The water itself consists of H⁺ and OH⁻ anion and they may act as standalone cation and anion enhancing the CO₂ sorption.

In thermal stability, the degradation temperature (T_d) and glass transition temperature (T_g) also increase after polymerization. From these results, we can see that the polymerization of AAILs enhanced CO₂ absorption as well as thermal stability. In thermal stability shows that anion plays a key role in thermal stability. By changing the anion type, thermal stability shows a great significant followed with cation type while cation modification has the least effect.

Therefore, these AAPILs can be considered as highly feasible for industrial application for CO₂ sorption in natural gas.

5.2 Recommendations

Functionalized ILs promising the higher CO₂ sorption and more research is need to further studies and understand their capabilities. In this research, by using amino acid as anions and polymerized the amino acid ionic liquids are the key factor of novelty to capture CO₂.

However, there are some recommendations which it could be useful to improve the progress of using ILs for CO₂ capture by modifying the existing ILs to enhance their properties.

- Functionalized PILs with diamino are tethered in cation and anion can be developed. These diamino properties would give higher CO₂ sorption. Literature has showed that with diamino ILs would give higher CO₂ sorption, however there were drawbacks due to higher viscosity of ILs. To overcome this, polymerizing the diamino ILs and convert to solid form would overcome this disadvantage.
- In CO₂ sorption, both chemisorption and physisorption are involved in AAPILs. In low pressure, the chemisorption took place and in higher pressure, the physisorption become the priority. These phenomena of increases of CO₂ sorption, needs to be investigated in more depth by taking into account the mechanism and type of anions in AAPILs.
- With the addition of water, the CO₂ sorption showed higher CO₂ sorption than dry AAPILs. This CO₂ sorption capacity should be investigated at higher pressure. The swelling behavior of AAPILs in the presence of water should be studied in depth accounting for all parameters that could influence the swelling. *i.e.* pressure, temperature, amount of water, density, volume of sample
- The absorption of AAPILs with CO₂ in low pressure involves chemisorptions where a new peak around 1600 to 1700 cm⁻¹ are formed showing a carbamic peak is formed. The forming of new peak should be studied by using *in-situ* of FTIR where the reaction of AAPILs and CO₂ can be study deeply.
- Natural gas consists largely of methane, ethane, propane, nitrogen, carbon dioxide, hydrogen sulphide, etc. Therefore selectivity of gases should be taking

into account. This is to study the capabilities of AAPILs to capture CO₂ in mixture of gases instead of in a single line gas.
