CERTIFICATION OF ORIGINALITY

This is to certify that I am responsible for the work submitted in this project, that the original work is my own except as specified in the references and acknowledgements, and the original work contained herein have not been undertaken or done by unspecified sources of persons.

MOHD AZLAN NORZAN

ABSTRACT

The project title is “GIS Application for Building Information Management”. The purpose of the project is to develop a GIS database in order to assist in building maintenance works. Maintenance is a very important activity especially for well-developed countries. For instant, Malaysia has a numerous number of high-tech engineering structures which require regular maintenance. They are Kuala Lumpur City Centre (KLCC), Kuala Lumpur International Airport (KLIA), Putrajaya Government buildings and Midvalley Megamall shopping complex; to name a few. Budget for maintenance works may be limited for each building. Thus, proper maintenance management should be done to minimize cost or to perform the maintenance within the given budget. The scope of the project will focus on several critical aspects in building maintenance, by preparing a database that is user-friendly and easily accessible by users. Users in this case refer to maintenance engineers and managers. In order to complete the project, research for raw data and drawing plans regarding building maintenance must be done. Then, this information will be inserted in a newly developed database using a GIS application. Learning GIS-based software is a very crucial task for this project. The GIS application chosen for this project is MapInfo Professional 7.0. Other than that, Microsoft Visual Basic .NET is used to manipulate the GIS data. The final product from the project is a system, which can assist the engineers and managers in building maintenance management.

ACKNOWLEDGEMENT

Bismillah ar-Rahmani ar-Raheem

In the Name of Allah, the Most Compassionate, the Most Merciful

Alhamdulillah, thanks to Allah, with His guidance and bless then, I managed to complete the Final Year Project entitled “GIS Application for Building Information Management”.

I would like to express my special appreciation to Dr. Abdul Nasir Matori, my supervisor; for his ideas and guidance, and giving me this opportunity to do this interesting project. Enormous gratitude goes to the internal examiners; for their comments and recommendations regarding the project.

I also would like to give special appreciation to Mohd Khairul Zarir Ahmed Lokman, Information Technology student; for his help in learning ArcView and Microsoft Visual Basic .NET. Special thanks to Miss Saadiah, Laboratory Assistant; for her assistance and help in understanding the MapInfo application.

Special acknowledgement goes to my parents; for their supports and motivation. Last but not least, thank you to all other parties or people who involve directly or indirectly during the period of completion of this project.

CHAPTER 1

INTRODUCTION

1.1. Project Background

Maintenance is very important after the construction of any building has been completed. Building maintenance is the process of keeping the building in a good condition to ensure its facade, durability and functionality.

Maintenance shall be done appropriately within the available budget. Proper database of the building will enable the maintenance process to be properly scheduled and prioritized. Hence, this will optimize the maintenance process using minimum budget. In real life situation, everybody will try to minimize the cost spent for building maintenance.

Using GIS application, the database containing information about the building will be easily accessible to the users. Checklists can be made directly from the computer application since the whole system has been computerized into a single database. Thus, maintenance process will be carried out properly.

The maintenance engineers save the hassle to check all maintenance data which are stored manually. Instead, by applying GIS to plan for building maintenance, the maintenance is expected to be carried out effectively within the given time frame and budget.

1.2. Problem Statement

Maintenance of a building could be costly and therefore it could be neglected due to the high cost. However, if there is a proper database (in GIS), such maintenance process could be properly scheduled and prioritized and hence optimize the maintenance process within the available budget.

1.2.1. Problem Identification

The problem arose when there is a maintenance budget limitation for a specified building. In order to perform the maintenance, managers or engineers need to prioritize which maintenance to be performed first. Improper prioritization might cause problems to the effectiveness of building functions; i.e. factories and schools. The author will cater the problem by proposing a system prototype development, using a GIS database.

1.2.2. Significance of the Project

The final product from the project is expected to assist the maintenance managers or engineers to properly schedule and prioritize maintenance works to be done within the limited budget. Hence, the effectiveness of the building functions will be preserved.

1.3. Objectives and Scope of Study

The objectives of this project are:

- To find and analyze the maintenance works required for a specific building.
- To develop a GIS database for a building for maintenance purpose.
- To create a system with a user-friendly interface and efficient to be used for building information management globally.

1.3.1. The Relevancy of the Project

Structures all over the world need to be maintained. Thus, this activity has become one of the major employment opportunities to the people worldwide. Structures like skyscrapers, bridges, highways and other engineering structures require regular monitoring and maintenance. Accordingly, any reduction in resources applied to building maintenance will have a visible effect on the national economy. This is due to the fact that in United Kingdom, it currently accounts for maintenance expenditure of approximately £20 billion (Technology Foresight Construction Sector Panel, 1995). Towards becoming a fully developed country, Malaysia is expected to possess many great buildings and structures which require high cost for maintenance, which includes civil and structural maintenance.

For this reason, this project is paying particular attention to the development of a new maintenance management approach aimed at reducing the maintenance costs of building. This project will describe a new, systematic framework for selecting a suitable maintenance strategy for each individual item in a building with the assistance from the GIS database. The exponential growth in computer development encourages the application of computer for all purposes.

1.3.2. Feasibility of the Project within the Scope and Time Frame

The scope of the project has been narrowed down, since the development of the database requires long period. The scope is divided under two parts, which are spatial data and attribute data.

Spatial data of the project is narrowed down to Building 13, instead of the whole UTP Academic Complex. On the other hand, attribute data to be covered are lighting and fire alarm system. Other data may be added as well to provide wider range of maintenance management. However due to the limited time frame, these aspects are not included within the scope. Examples of other aspects are building structure (columns and beams), floor tiles, glass panels, doors, windows and elevator.

CHAPTER 2

THEORY / LITERATURE REVIEW

2.1. Definition of GIS

A Geographical Information System (GIS) can be defined as a system for capturing, storing, checking, manipulating, analyzing and displaying data, which are spatially referenced [1]. From the U.S Geological Survey, GIS is a computer system capable of assembling, storing, manipulating and displaying geographically referenced information. Raw geographically referenced information, which is geographical data stores information about the location, shape and attributes of real objects. These data gathered and captured in digital form so that it can be used to store and reproduce as useful information. The power of computer enables this information to be manipulated, updated and analyzed in many different ways. [5]

2.1.1. GIS Evolution

Geographical analysis started since 1930s and 40s where different types of maps of the same area were overlaid. In 1950, Tyrwhitt invented the technique of map overlay. It is a technique where maps were traced onto transparent overlays for use in land analysis and presentation. It does not just stop there where in 1962; two planners at Massachusetts Institute of Technology had evolved the map overlay idea into weighing, by making the overlays different in their importance with respect to each other (Keith C. Clarke, 2001, p.10). When the usage of computer becomes familiar around 1959, many computer programs were developed to draw map using primitive printers and plotters. Since then, a lot of computer programs had been developed for map digitization and geographical data analysis and manipulation. DIME (Dual Independent Map Encoding) is the major

breakthrough in the history of geographic information representation. DIME together with the resultant files, called Geographic Base Files (GBFs) recognized that attribute information which is all the data collected and computer map used in planning could be integrated for mapping and search for geographic pattern and distribution which later known as data mining. Hence, it is clear that since 1950s systems have evolved to convert map into digital form and until now being used for analysis and problem solving.

2.1.2. Spatial and Attribute Data

All GIS analysis begins at the same point; you have to know what you need to know. The process of answering this question inevitably leads you to make decisions about the information that is relevant to the task. For this reason, it can be said that data is at the heart of every GIS project. Depending on the data that is presently maintained (databases, spreadsheets or other files), you may have much of what you need on hand. Usually, however, you will have to obtain at least some information from outside sources. In order to do this, it is very important to know two main categories of data used in GIS.

A GIS integrates two fundamentally different types of data. One type defines the shape and location of places -- this is called spatial data. The other type describes those places, and the people who live in them and the things that happen there – this is called the attribute data. Put succinctly, spatial data enables you to draw a map; attribute data makes the map meaningful.

Although they are structurally different, spatial and attribute data live symbiotically in a GIS, and it is hard to talk about one apart from another. The map files you get from commercial and non-commercial sources normally include both.

2.1.3. Vector, Raster and Image Data

Spatial data itself can be divided into three types. The most common type in GIS is called vector data. Vector data represents geographic features as either points, lines or polygons.

Polygons tend to be used for sizable area like countries or ZIP codes; lines or things like streets and rivers; and points to represent specific locations.

Raster data takes a different approach to the mapping problem by dividing geographic space into a matrix of identically-sized cells. Each cell is linked to a number that stands for some geographical property (i.e. “1” for land, “2” for sea and “3” for shore).

The third type of data is image data, which includes such things as satellite and aerial photographs, and optically scanned paper maps. Strictly speaking, image data is a kind of raster data, because an image is composed of uniformly-sized cells (pixels) linked to specific numbers – numbers that represent a color or grayness value. Image data can serve as a visual backdrop to vector data. It can also be used to create vector data through a digital tracing process, or even for analysis in a discipline known as remote sensing.

2.2. GIS Application in Modern World

“Geographic Information Systems (GIS) have appeared in business in the last decade. While growing at a rate of 20-30% per year (Daratech, 1995), some observers argue that GIS is under-exploited by business for competitive advantage (e.g., Castle, 1993a). Can GIS contribute to competitive advantage? Framework for global strategy is used to explore how GIS technologies may contribute to strategic choices and therefore to competitive advantage.”

“GIS enables yet another approach: conceiving of geography not as a constraint, but as a variable to be manipulated and managed.”

Lisa D. Murphy [4]
School of Business, Indiana University, Bloomington IN
limurph@indiana.edu

"When the UDS GIS Committee began its task of selecting a pipeline information system, we were well aware of the broad range of options available for our consideration. None of us were GIS experts. We had only broad directives regarding system functionality. Our budget was limited, and we were quite sure that a million-dollar solution would never receive approval. In addition to the many commercial GIS alternatives, we were being asked to consider a data management system being developed internally. The challenge before us was considerable."

Gerald Childers [4]

Ultramar Diamond Shamrock Corporation (UDS)
P.O. Box 696000, San Antonio, Texas 78269-6000

"As the GIS Committee was beginning its deliberations, some of our members were exposed to an Internet GIS program from Autodesk. Because we used AutoCAD already, we felt fairly comfortable in looking at a GIS product from Autodesk. The product was called MapGuide and was shown to us. The developed application we were shown was a GIS for a pipeline system. And, among the capabilities demonstrated were hypertext links to documents from a base map of the pipeline system. The fact that MapGuide ran in a browser like Netscape's Navigator or Microsoft's Explorer was also appealing to us. It appeared that the MapGuide system would allow us to use the documents we had already scanned. It would also allow us to use them as we had originally intended. Since the program ran in a browser, it seemed obvious to us that it was easy to learn and easy to use. "Ease of use" was very important to us."

Robert Keating [4]

Topographic Engineering Company
6709 N. Classen, Oklahoma City, OK 73016

2.3. The Project From Civil Engineering Perspective

2.3.1. Building Maintenance

Building maintenance can be classified into two categories, planned and unplanned. Under these two categories, the maintenance can again be divided into preventive and corrective maintenance.

Planned maintenance consists of list of works which are expected to be done in a maintenance cycle. Unplanned maintenance is the list of works which have to be carried out beyond the plan due to unexpected errors or failures. Preventive maintenance is done to prevent damages, while corrective maintenance is done to bring the item or equipment back into functionality from errors or failures. Scheduled maintenance is done periodically based on the schedule. On the other hand, condition-based maintenance is done when the condition of the item or equipment is below par. [8]

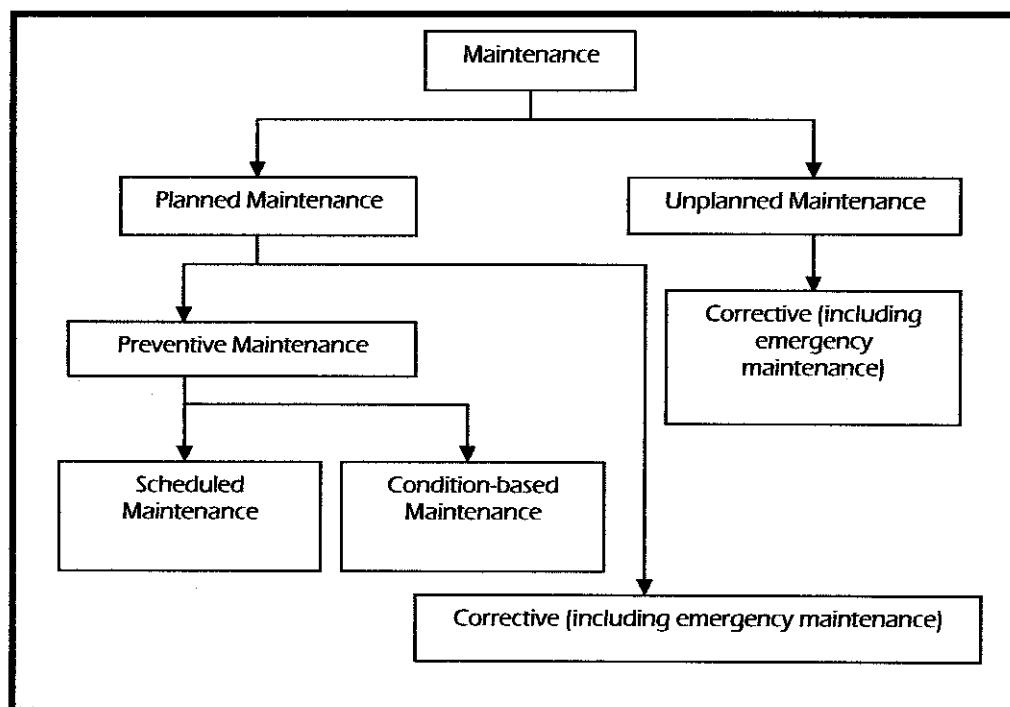

Figure 2.1 Types of Maintenance

2.3.2. GIS in Geomatics Course

GIS is first introduced to Civil Engineering students in Geomatics course. The term is usually related to GPS. GIS and GPS are widely used in fields related to mapping system and position coordination. The students are also introduced to one of GIS softwares, MapInfo 7.0 Professional. However, the students are not exposed to the usage of the software thoroughly.

Map digitization is the basic building block for GIS function. By having digitized map, only then other GIS functions can take place by manipulating this map. Map digitization is one of the methods for geospatial data collection besides surveying and remote sensing. Maps are digitized by converting paper maps into electronic form using digitizer such as scanner. Surveying on the other side is the more complex and complicated way of geospatial data collection. Measurement of an area is taken directly from the real world, which involves direct intervention from surveyors within the area to be digitized. Traditionally, people use physical tools such as chains and tapes to measure distance or a device called theodolites to measure direction. But, with the emerging of Global Positioning System (GPS), data capturing become more reliable and accurate. It enables positioning of objects on or above the earth surface in an absolute sense. Furthermore, the usage of satellite in GPS replaces the role of surveyor in site measured leaving the surveyor with less hassle computerized surveying activities.

Remote sensing is another method for data collection. It uses aerial and space imagery to record geographical information with the help from additional sophisticated devices. It includes the interpretation of additional phenomena such as land type by detecting Earth's reaction to different wavelengths of electromagnetic radiation.

2.3.3. MapInfo as the GIS Software

MapInfo Professional version 7.0 is the latest release by MapInfo Corporation of their desktop GIS software product. MapInfo organizes all its information within the software in the form of tables that are stored with a .tab extension. For instance, when opening up an Excel spreadsheet in MapInfo, the software will automatically create a .tab file which describes the structure of the Excel data without modifying the Excel table. Tables that include spatial features have a .tab extension, but the graphic features are stored in a file with a .map extension. MapInfo can open tables from Microsoft Access and Excel, dBase, delimited ASCII, Lotus1-2-3, ESRI shapefiles, and Raster and Grid images. Tables remain open in Mapinfo until the user close the table from using the File-Close Table menu. Mapinfo stores the configuration of the open tables and windows into a workspace file (.wor). [2]

MapInfo allows the users to create a thematic map by allowing the usage of digitized maps or raster images. Symbols are onto the maps by simply clicking on the maps after setting the type of symbol to be used, one at a time.

2.3.4. GIS Approach versus Traditional Approach in Building Maintenance

Advantages of using GIS approach are obvious compared to the traditional approach. GIS approach uses a system to store and manipulate the maintenance data. Meanwhile, traditional approach requires manual access to the databases, spreadsheets or files containing the maintenance data. Advantages of using GIS approach are listed below:

- Better data accessibility.
- Systematic and convenient storage of database.
- Time saving for maintenance planning.
- Better accuracy in decision making. [3]

2.4. The Project from IT Perspective

2.4.1. Software Engineering

This project is an interdisciplinary activity involving knowledge drawn from different backgrounds. This knowledge is required to consider all implications of the system design.

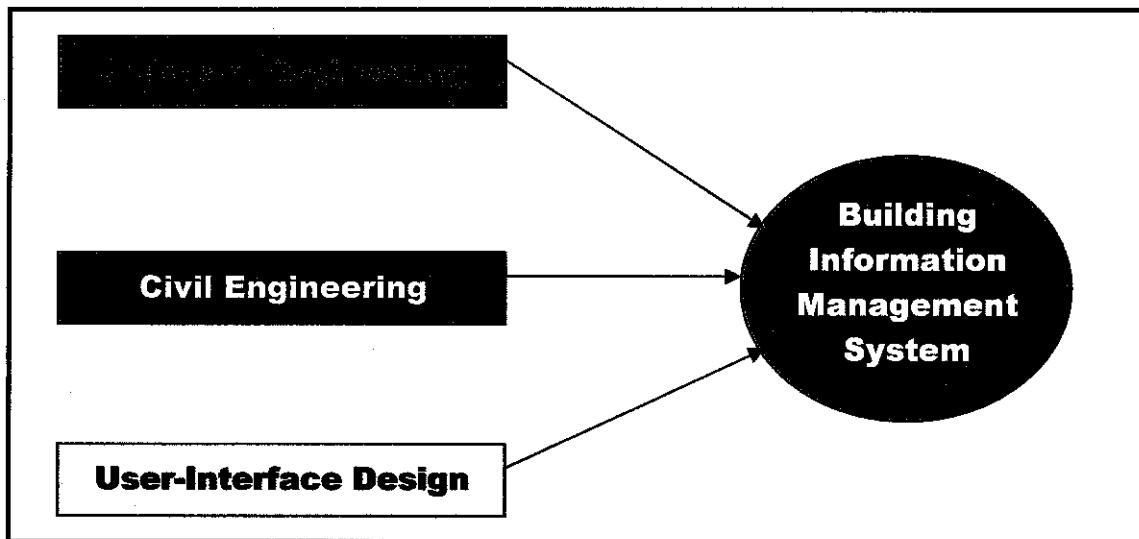

Figure 2.2 Interdisciplinary Involvements in the Project

Because software is inherently flexible, many unexpected problems are left to software engineers to solve. Software engineers are often left with the problem of enhancing the software without increasing the hardware cost. The solution may be to enhance the processing capabilities of the software. [7]

However, in this project, the main concern is to accommodate the decision making decision for maintenance. Therefore, there is no limitation to the design of the system.

CHAPTER 3

METHODOLOGY / PROJECT WORK

The methodology on how the project was conducted is discussed in this chapter. The preliminary research was conducted to get the overview of the topic and to design the milestone or Gantt chart. This project is planned to be completed in two semesters. The first half of the semester was used to concentrate on the data collection and the project interface design. In the second semester, focus is given on generating the database using MapInfo and integrating it into VB.

3.1. Procedure Identification

The approach used for this project is a cycled process. It is called System Development Life Cycle (SDLC). Although the SDLC model has been followed, the author has chosen to eliminate one part of the process, which is operation and maintenance. Thus, there are four phases involved; Research and Analysis, Design, Implementation, and Integration and Testing.

3.1.1. Research and Analysis

In this phase, the author did a study and research regarding the requirements of the project. The author also did research on GIS and current building maintenance management practice. The author discussed with the supervisor on how the system will be and the features that need to be included. The scope of the project was also identified during the discussion.

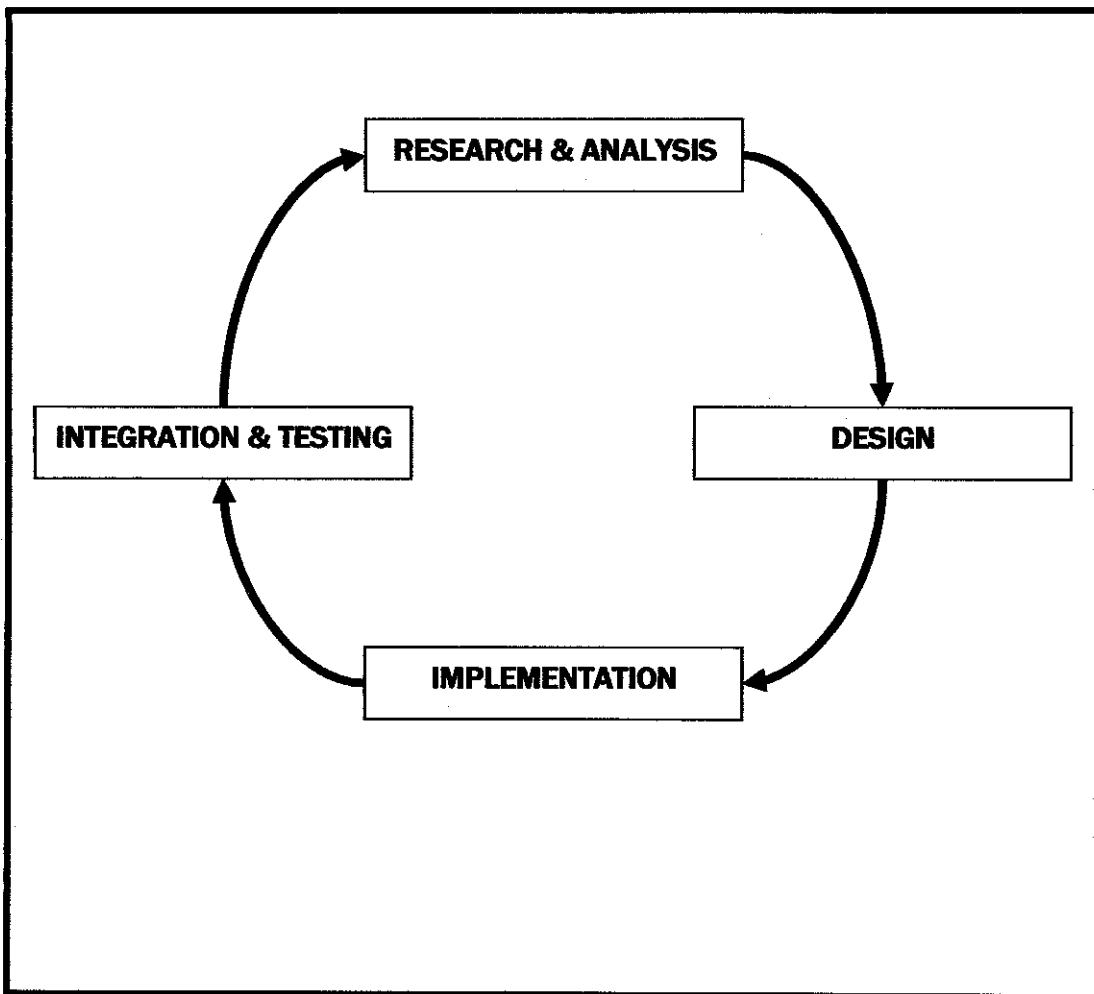

Figure 3.1 SDLC Approach for the Project

The author also learned how to use softwares related to the project, such as AutoCAD 2002, MapInfo 7.0 Professional, Microsoft Visual Basic .NET and ArcView 3.2. The expertise of using these softwares is very crucial for the development of final product.

Data acquisition was done during this phase. Data required for this project are UTP maps and maintenance data. The data are obtained from KLCCB Document Control Unit in form of AutoCAD drawings.

3.1.2. Design

During the design phase, the first thing to be created is the GIS database, using MapInfo. In order to manipulate the database, VB is used. The final product expected from the project is a system or program, which enable the user to manipulate the data for building maintenance purpose. VB is used since MapInfo does not allow variation in data manipulation.

User-interface design is very important for the system. The flow of the system must be easily understood. Items featured in maps in the system should be easily identified. Manipulation of data must be arranged properly to allow viewing and modifying.

3.1.3. Implementation

This is the phase where the GIS databases are prepared and the VB codes are generated. Data from AutoCAD files are converted into MapInfo tables manually by the author. While doing the coding process, the author needs to check the codes by debugging the codes from time to time. If the codes are free of errors, the pages will display successfully. Otherwise, the error will be displayed on VB error browser.

3.1.4. Integration and Testing

Integration is the process where the database and the system are integrated to enable the manipulation of data. When integration process takes place, bugs and errors will always be found. The existence of bugs and errors require the author to test the system from time to time to eliminate all these bugs and errors.

3.2. Tools / Equipments Used

In order to construct the final product, there are several tools used.

3.2.1. Computing Facility

The computing facility is provided by the student with the capability to run the required softwares, preparing reports, accessing data, learning GIS application and presenting the outcome of the project. The computing facilities are equipped with softwares to assist the progress; for example, Microsoft Word, Paint and AutoCAD 2002.

The computer facility specifications are as followed:

- Platform: Microsoft XP Professional, supports .NET Framework version 1.1
- Processor: Intel Pentium IV 2.53 GHz
- Memory: 1GB RAM
- Hard drive: 80 GB
- Compact discs for data storage
- Internet Explorer version 6.0

3.2.2. Development Tools

Development tools are softwares used during the implementation phase of the project.

- AutoCAD 2002
- MapInfo 7.0 Professional
- Microsoft Visual Basic .NET

3.2.3. Building Maintenance Data

Building maintenance data are required to prepare the database for the application. The data are in form of AutoCAD drawings and are extracted by the author into MapInfo tables. Pictures and records are made from time to time for every item included in the project.

CHAPTER 4

RESULT AND DISCUSSION

The final product from the project is a stand-alone system which allows the users to access and manipulate the database to do maintenance planning. The system is named as “Building Information Management for UTP Academic Complex (BIMUTP)”.

4.1. Flow of the System

Flow of the system shows how the users are going to use the system. It starts from when the user starts running the system until the user quits. While using the system, users can move from page to page and give specific task the system. By creating the flow of the system, it allows the system administrator to monitor the system performance and recommends any upgrades or changes. The flow is shown in Figure 4.1.

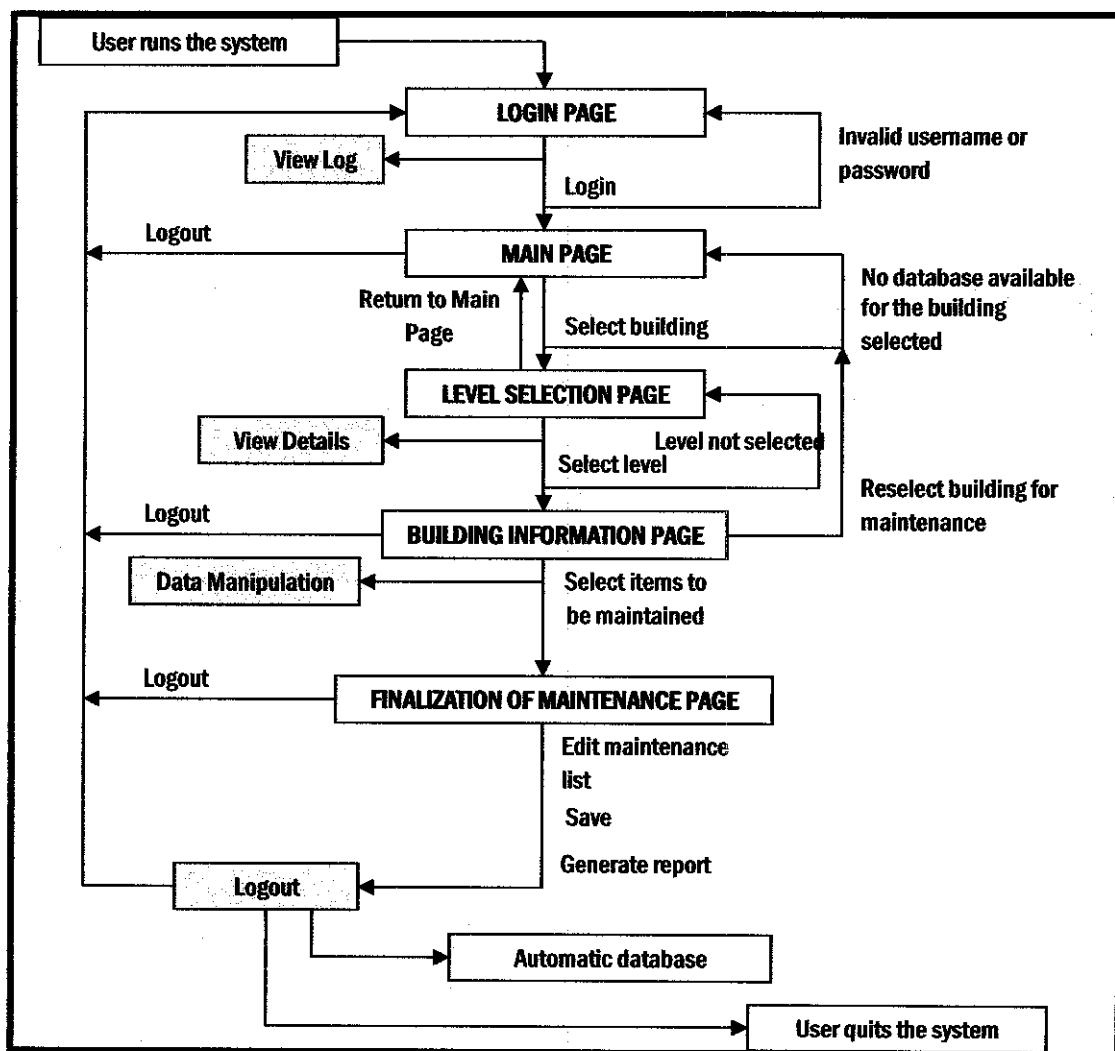

Figure 4.1 Flow of the System

4.1.1. User Login Page

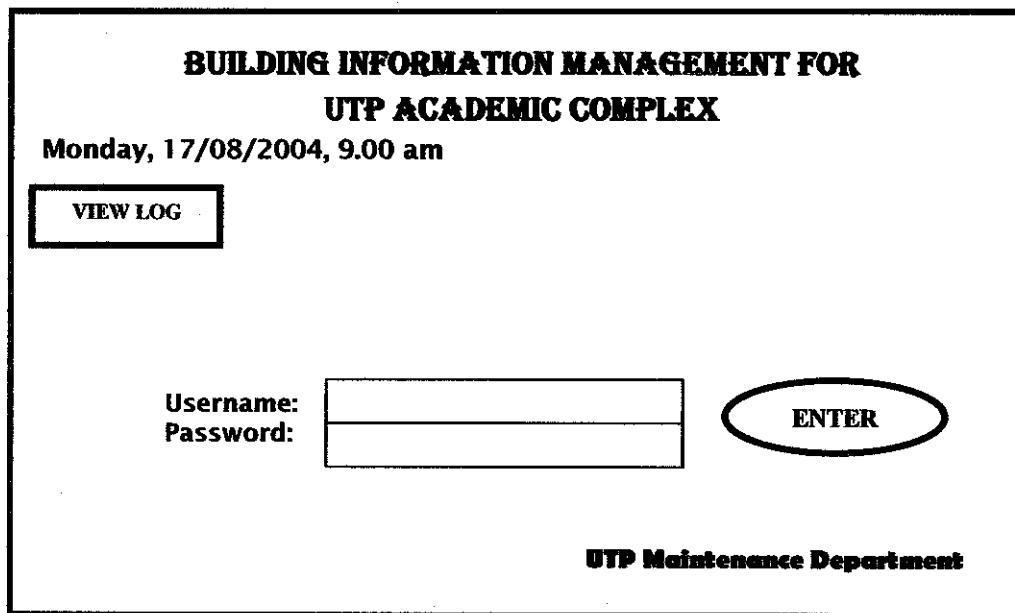

Figure 4.2 User Login Page

User Login Page (kindly refer to Figure 4.2) requires the user to login using the given username and password. The purpose of this page is to prevent unauthorized access to the system. By viewing the login log, the administration is able to identify the person who makes any changes or updates to the maintenance database. Precisely, only people with specific tasks can access the database and make any changes to it.

By clicking on the 'VIEW LOG' button, a small window will appear, showing the previous logins to the system. The 'ENTER' button will redirect the user to Main Page.

Date and time are shown since the data are stored in descending time-based sequence. The Login Log consists of username, date and time of login. Thus, the person who access the system has the responsibility upon the system while he is logged in.

4.1.2. Main Page

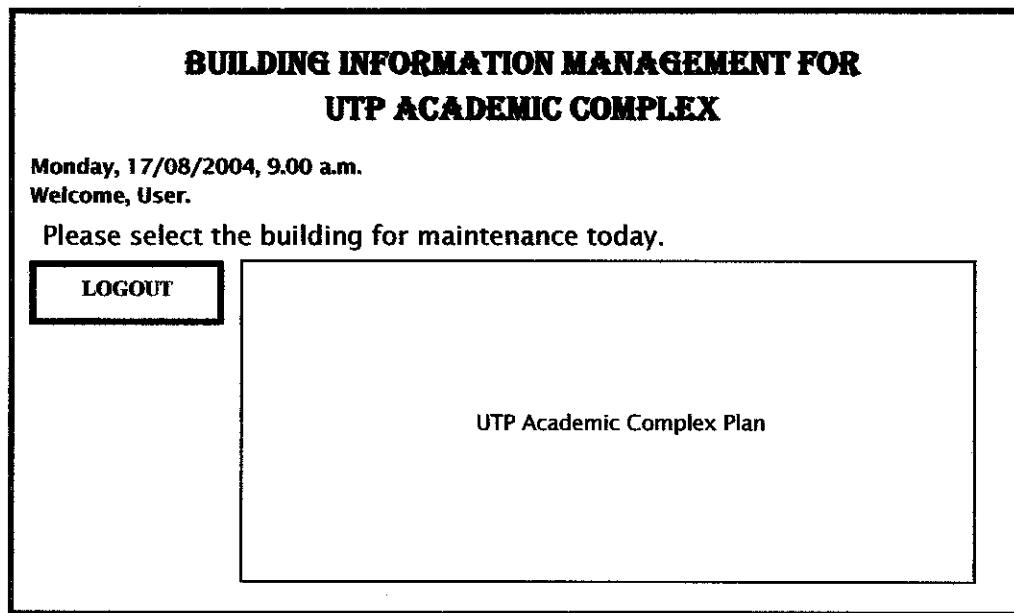

Figure 4.3 Main Page

In Main Page (kindly refer to Figure 4.3), the user is required to specify the building to access its information. The selection will be made by clicking on the building that the user wishes to access. Later, the user will be directed to Level Selection Page.

4.1.3. Level Selection Page

In Level Selection Page (kindly refer to Figure 6), the basic information about the selected building will be displayed. The user can view the details about the building by clicking on the "VIEW DETAILS" button.

The user is required to choose the specific level to view the maintenance data. By clicking on the "SELECT" button, the user will be directed to the next page.

Other buttons are "MAIN" and "LOGOUT", which respectively enable the user to return to the Main Page and logout from the system.

BUILDING INFORMATION MANAGEMENT FOR UTP ACADEMIC COMPLEX			
Monday, 17/05/2004, 9.00 a.m.			
<input type="button" value="MAIN"/> <input type="button" value="LOGOUT"/>			
You have selected:			
Building: Department:	<table border="1" style="width: 100px; height: 60px; vertical-align: top;"> <tr> <td style="text-align: center; padding: 5px;">13</td> </tr> <tr> <td style="text-align: center; padding: 5px;">Civil Engineering</td> </tr> </table>	13	Civil Engineering
13			
Civil Engineering			
<input type="button" value="VIEW DETAILS"/>			
Please select the specific level to access the database.			
<input type="button" value="Level 0"/>	<input type="button" value="Level 1"/>	<input type="button" value="Level 2"/>	<input type="button" value="Level 3"/>
<input type="button" value="SELECT"/>			

Figure 4.4 Level Selection Page

4.1.4. Building Information Page

Building Information Page is the “heart” of the system. The user is allowed to access the database from this page to assist the decision making process (i.e. maintenance works to be carried out).

The level floor map will be displayed in this page (kindly refer to Figure 4.5). The user will select the type of maintenance to be shown on the map by marking the layers that they want to view. List of layers available are provided in the Layer Control box. The maintenance types are put in different layers, named Lighting, Fire Alarm System and Room Information.

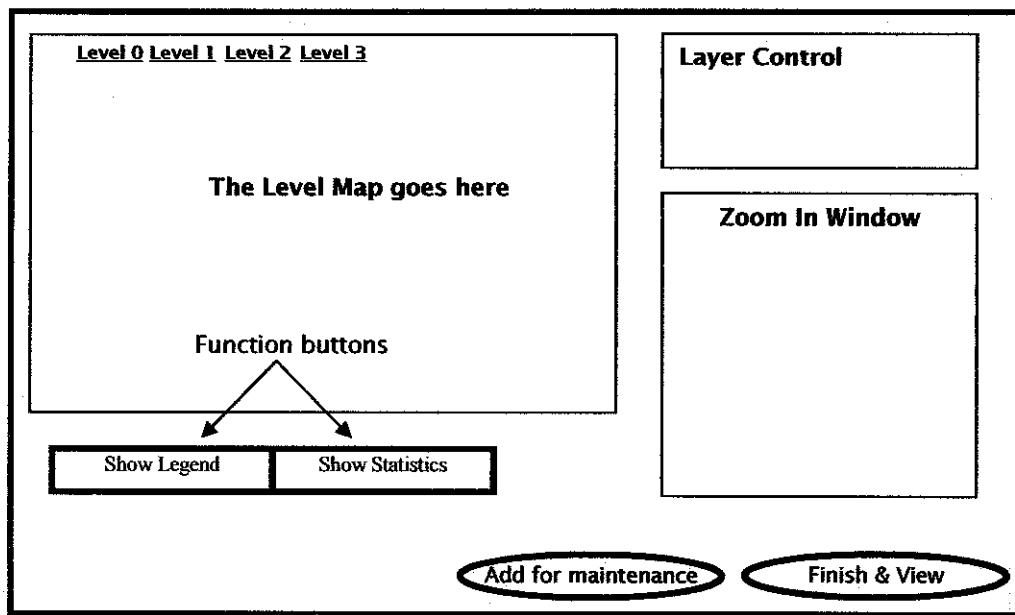

Figure 4.5 Building Information Page

The function icons will assist the user in exploring the map. These functions are adapted from MapInfo application. The functions to be added are listed below:

- Show Legend – show the legend for all symbols on the map.
- Show Statistics – show the statistics for all items in the building.

In this page, the user will be able to select the item on the specific floor and view the information of each item. Details to be included for an item are as followed:

- Item
- Item code
- Location code
- Status
- Note
- Last change or service
- Next change or service
- Cost

- Supplier
- Contractor

By clicking on the “ADD FOR MAINTENANCE” button, the item will be added to the maintenance list. When clicking the “FINISH & VIEW” button in the Level Selection page, the user will be directed to the Finalization of Maintenance Page.

4.1.5. Finalization of Maintenance Page

Monday, 17/05/2004, 9.00 am				
List of items to be maintained:				
Item:	Location Code:	Expected Completion:	Next Maintenance:	Cost:
Total Cost: <input type="text"/>				
Confirm the list?				
Add more items		Cancel all works	Finish and Print	

Figure 4.6 Finalization of Maintenance Page

In Finalization of Maintenance Page as shown in Figure 4.6, the user will enable to check the maintenance list of items selected earlier. The cost of maintenance for each item will be shown, which will sum up to determine the total cost. The maintenance works can be added or removed from the list.

If the user wants to add other maintenance works, the ‘ADD MORE ITEMS’ button will redirect the user to the Level Selection page. ‘CANCEL ALL’ button will erase all the

maintenance works. To save the list of maintenance works, the user may click on the 'FINISH AND SAVE' button. The list of maintenance works to be done in the month will be saved.

In the same time, the maintenance database for the system will be automatically updated.

4.2. Graphical User Interface (GUI) Considerations

Three elements have been considered by the author in designing the GUI for the system. They are balance, unity and movement.

4.2.1. Balance

The user interface is designed to be a well-balanced interface. There are two types of balance; symmetrical and asymmetrical, as shown in Figure 4.7 and 4.8.

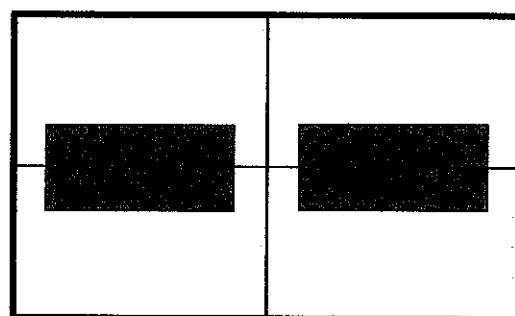

Figure 4.7 Symmetrical Balance

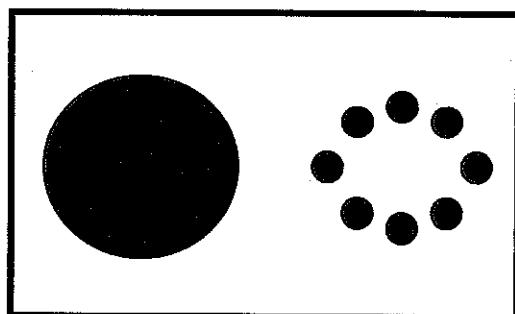

Figure 4.8 Asymmetrical Balance

4.2.2. Unity

Interface unity refers to the design consistency of intrapage and interpage unity. For intrapage unity, take buttons as example; same color and font are assigned to them.

On the other hand, for interpage unity, take button locations for example; they are located at the same place on every page. For example, “LOGOUT” button is always located at the top left side in the window.

This interface unity can be identified as shown in Figure 4.9 and 4.10.

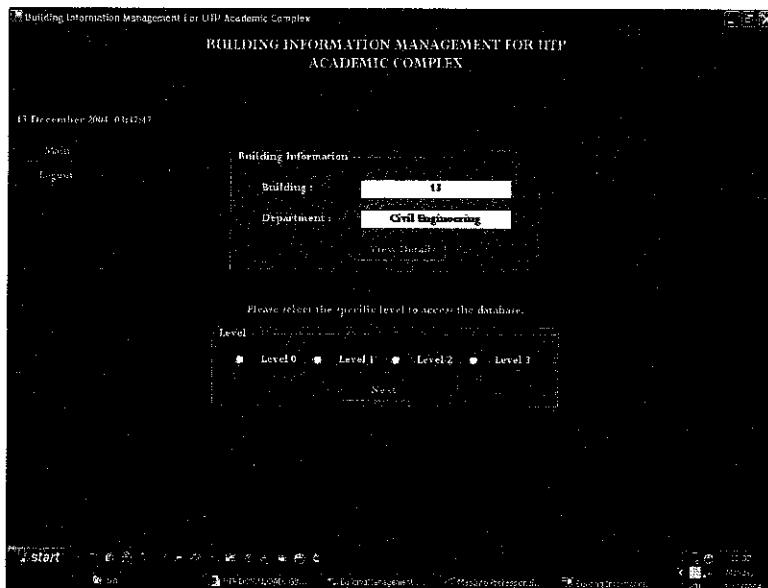

Figure 4.9 User Interface for Level Selection Page

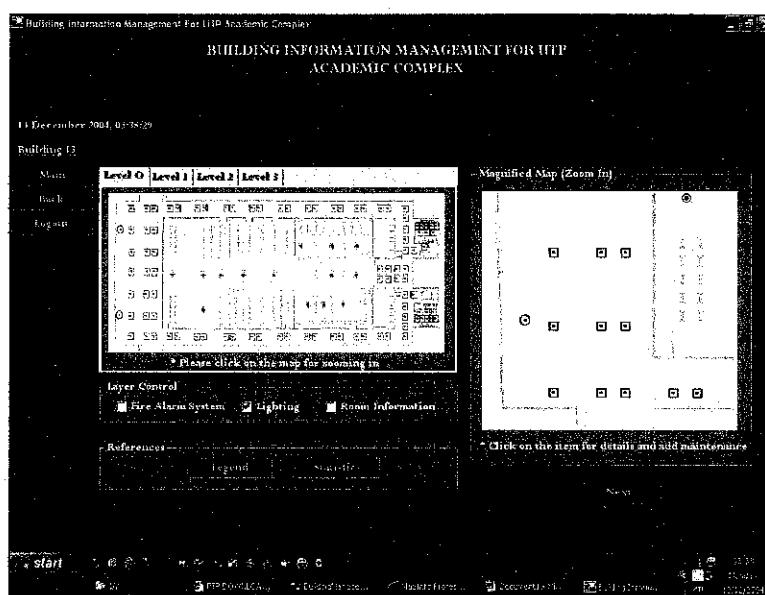

Figure 4.10 User Interface for Building Information Page

4.2.3. Movement

The movement of information flow is designed top-down, from left to right. In such way, transportability of knowledge will be preserved.

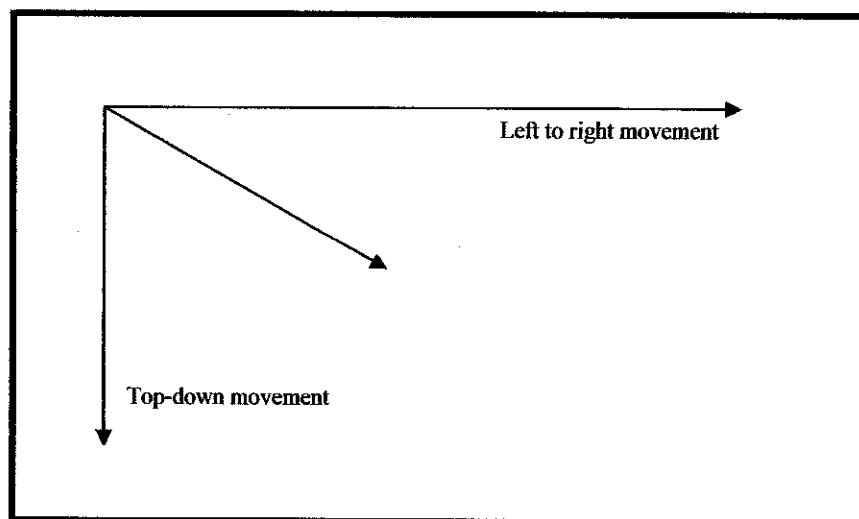

Figure 4.11 Movement of Information Flow within a Page

4.3. Databases in BIMUTP

Database is the heart of the system. The manipulation of the data is designed in such way that they are easily accessed and understood. The database will automatically update itself when the users give the instruction. Logging is also done for the database to identify every change in the database.

The database for BIMUTP consists of spatial and attribute data as shown in Figure 4.6.

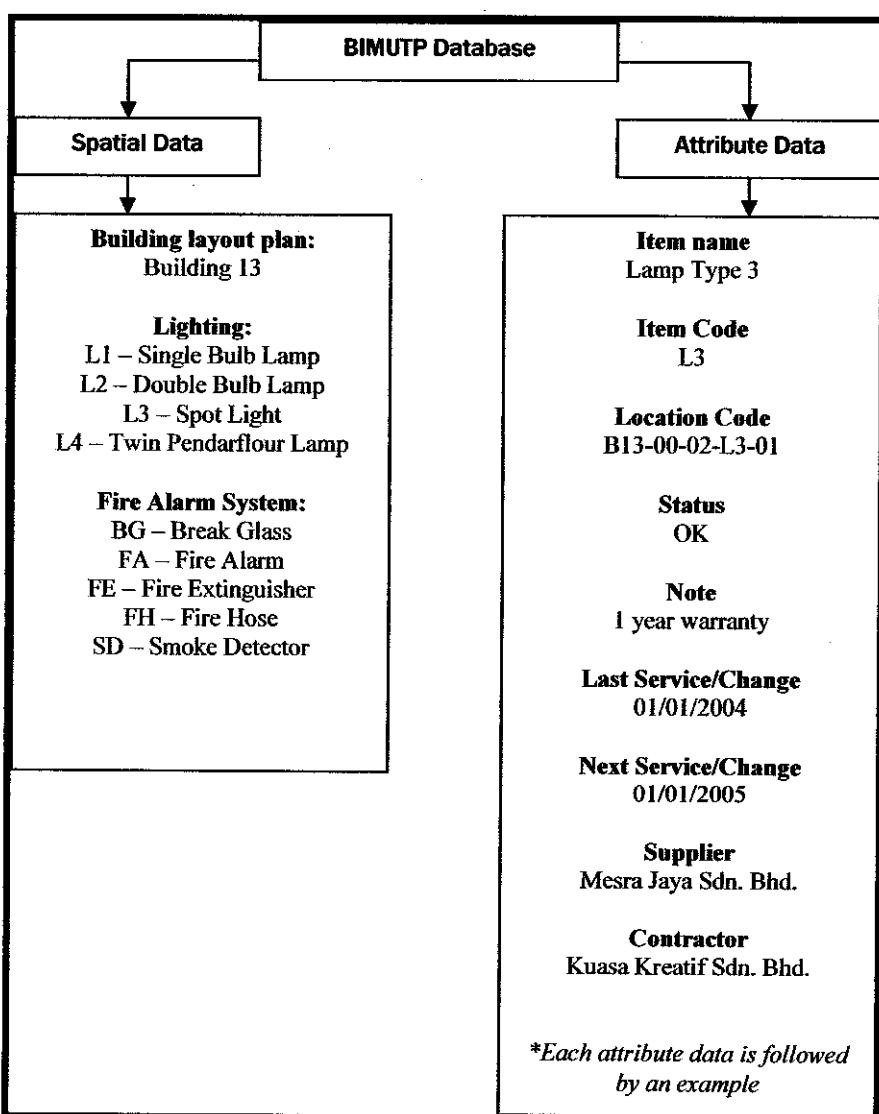

Figure 4.12 Elements in BIMUTP Database

4.4. User Access

The limitation of access to the system is created to secure the database within. Only authorized people can access the system by providing password that matches the username.

Login log is provided to enable the system administrator to track the users who have logged in the system. By having this log, the users can also view the last time when the previous users have logged in.

4.5. Error Handling Feature

In order to assist the users in using the program, a message box will appear when there is an improper usage of the system. This message box will remind the users if they miss any necessary action or perform an action restricted by the system.

Error handling feature is very important to guide the users to follow the flow of the system.

CHAPTER 5

CONCLUSIONS AND RECOMMENDATIONS

5.1. Conclusions

At the end of the project, the author has fulfilled the objectives set earlier in the planning stage. The project requires the author to master the IT knowledge in order to implement the system design. This process has given the opportunity to the author to learn deeply about GIS.

Interdisciplinary cooperation is very important. In real life, in order to implement the GIS database system, civil engineers must cooperate with software engineers and user interface designers to come up with a system that can fulfill the engineering requirements.

The author also realizes that GIS is a widely used method for many purposes such as management, business planning, marketing territories, demographic characteristics and strategic allocation. Thus, by doing this project, the author is implementing the possibility for a new approach in building maintenance management instead of the traditional approach.

As the final conclusion, building maintenance management using GIS approach is better than using the traditional approach in terms of data accessibility, storage convenience, time duration for maintenance planning and accuracy of decision making process.

5.2. Scope Expansion

Since the time frame is limited, the scope has been narrowed to Building 13; covering two types of items; lighting and fire alarm system. The system has been designed in such way that its database can be easily expanded. In the future, it is recommended that the scope to be widened to cover the whole UTP Academic Complex as shown in Figure 5.1. The types of items covered should also be expanded; i.e. the power system, air-conditioning and ventilation, restrooms, lecture theatre, and also the landscape.

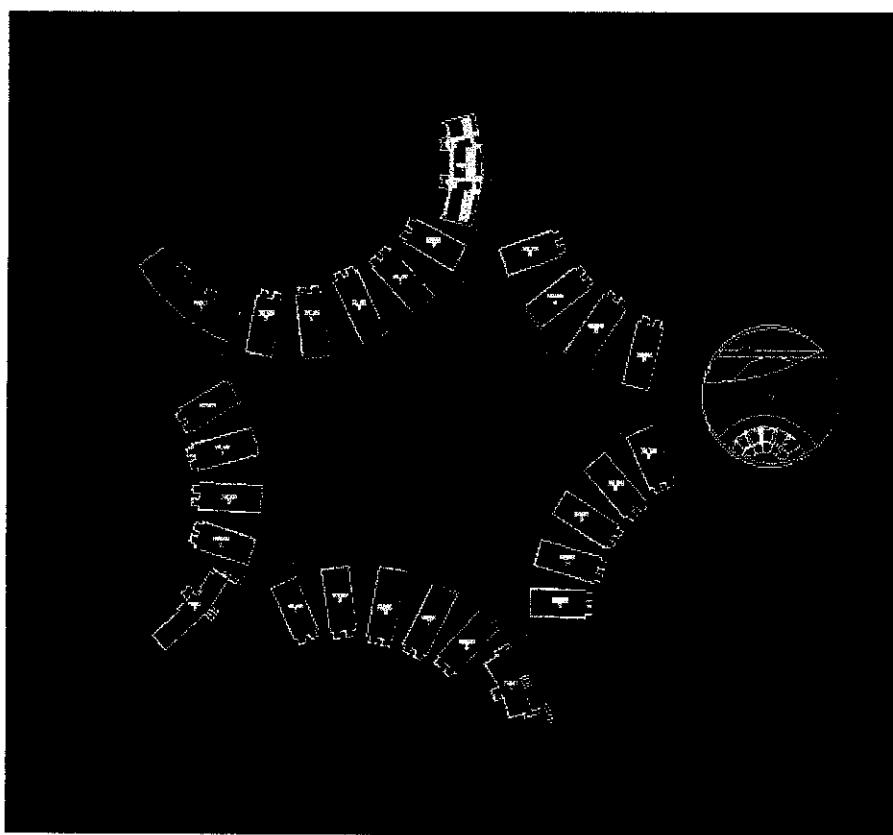

Figure 5.1 UTP Academic Complex

5.3. Revision of Data Manipulation Features

The author also would like to propose the revision of data manipulation features presented in the system. Current features available are user login, login log, statistics, summation of total cost and maintenance log.

The revision of these features must be done in order to accommodate the actual needs of maintenance engineers and managers. The needs may differ from one building to another.

5.4. Usage of ArcView Application

For this project, the author chooses to use another database format instead of MapInfo format (.tab) in order to enable the data to be manipulated easily by VB. The author would encourage the usage of ArcView application for the database integration.

Until this report was written, the author is still unable to acquire the coding for the integration. In order to create a user-friendly application, the author must determine the way to integrate the MapInfo with another application. VB is well-known as the software to create a stand-alone program. Thus, the usage of VB will enhance the performance of the final product in term of appearance and functionality. The best way to integrate the database into the system is by converting it into another format (.shp) that can be opened in ArcView application. VB possesses the capability to manipulate the data from ArcView using an add-on feature called MapObjects. However, the computer facility owned by the author rejected the installation of ArcView application. For future expansion, the usage of ArcView is mostly encouraged by the author.
