## CERTIFICATION OF ORIGINALITY

This is to certify that I am responsible for the work submitted in this project, that the original work is my own except as specified in the references and acknowledgements, and that the original work contained herein have not been undertaken or done by unspecified sources or persons.

---

(Hasniza binti Zainal)

## **ACKNOWLEDGEMENT**

First of all, deepest gratitude to Allah SWT for His bless in various aspect to accomplish the final year project entitled 'Effect of Palm Oil Fiber on Mechanical Properties of Polystyrene'. Nothing will be happened without His permission in accomplishing this final year project.

Secondly, thousands appreciation are dedicated to my beloved parents for their commitment and permission. They were a big supporter behind all scenes, and are the best source of inspiration ever had. All their support had firing up the spirit in finishing the entire job structured by my supervisor.

In accomplishing these 2 semesters project, a big acknowledgement is given especially to my supervisor, Associate Professor Dr. Faiz Ahmad, for all his supervision and consultation. Acknowledgement is also given to all Materials Department technicians and fellow colleagues who were directly involved in this project for their best cooperation. The commitment towards the accomplishment of this project is highly appreciated.

## ABSTRACT

The effect on various mechanical properties of microstructures and physical properties of the polystyrene filled with different amount of oil palm empty fruit bunch fiber were investigated. The polystyrene reinforced with palm oil fiber composites observed the variation of the mechanical properties. For treatment of the fiber, NaOH and distilled water were used to ensure that the fibers were disaffected from dust and contamination. The fibers were dried and powders of EFBF were compounded with polystyrene in a co-rotating twin screw compounder. The composites feedstocks were injection molded by the specific molding temperature and pressure to produce the dog bone shape test sample. The test samples were tested with the tensile testing machine according to the ASTM standard to test the elasticity and modulus of the new composites. The microstructures composition were observed using the SEM and showed the different of microstructure characterization. Scanning electron microscope micrographs showed that the particles dispersed in the matrix. This project was identifying the percentage of volume fraction of reinforcement and polymer matrix was affecting the properties of the composites polymer.

## CHAPTER 1: INTRODUCTION

### 1.1 Background

The plastic reinforces composites industries for application such as food packaging, transportation and construction have been established since early 1960s. The quick changes in research and development have led the material scientists and industries to expand the environmental friendly composite materials. As a result, natural fiber such as oil palm fiber, coconut coir and rice husk, are getting attention as reinforcement in polymer matrix. To the agro-based industry, this oil palm fiber have been utilize as boiler feedstock in the oil mill to recycle the waste of the fiber. In Malaysia the amount of Oil Palm Empty Fiber Bunch Fiber (OPEFBF) waste generated by the palm oil industries is very high, which is can be estimated approximately 8 million tons per year.

Composite materials owe their extraordinary uniqueness to the fibers which are used to reinforce the matrix. The combination of two very different phases, the matrix medium which is polystyrene and the empty fruit bunch fibers EFBF, allow a huge level of elasticity in the growth of microstructure arrangements. In addition, when fibers coupled with their polymer's mechanical strength and stiffness, it will let the natural structures to be better reinforced in areas of greater stress. One of the biggest new areas of research in this reinforced composite is in combining natural fibers with polymers. Although, prices for plastics have risen over the past few years, combination natural fiber to plastics provides a cost reduction to the plastic industry but in some cases, it wills increases performance as well. To ensure that the fiber can be utilized as reinforcement, an efficient study of the behavior of oil palm fibers will be investigate. [1-2]

## **1.2 Problem statement**

Most of the reinforcing fibers such as glass and carbon are non-biodegradable and non-recyclable. Utilization of OPEFBF in packaging industry not only help solving environment problems related to the disposal oil palm fiber wastes, but also help packaging industry to produce environmental friendly biodegradable packaging materials. For this disadvantages that occur for the current use of polystyrene, this project will be improve the properties in term of the mechanical properties of tensile strength and modulus of elasticity of the polystyrene when reinforced with fiber. Thus, it can be modified at the composite properties between the natural fibers and the polymer matrix which lead to the weakening the composites. In other hand, this paper will be study the percentage of natural fiber which is the Oil Palm Fiber and Polystyrene can be cooperate to produce the composites, which known as a biodegradable product. [3]

From the study and researches, there are various disadvantages when using the polystyrene as main composites for their applications. There are:

- Poor solvent resistance.
- Subject to environmental stress cracking.
- Not suitable for microwave applications.
- Not suitable for freezer applications.
- Poor barrier properties.

### **1.3 Objectives**

- To investigate the potential of Oil Palm Empty Fruit Bunch Fiber as a reinforcement for the polystyrene.
- The purpose of this project is to study the effect of percentage in volume fraction between oil palm fibre reinforcement and Polystyrene.
- To study the effect on mechanical properties of tensile strength, modulus of elasticity and also the microstructure of the composites.

### **1.4 Scope of Study**

This project is covering the study in agro based fibers which is using the empty fruit bunch fiber (EFBF) of the palm oil. It also includes the studies of the performance of the palm oil and their exploitation as a fiber in polymer composites. The fiber and Polymer will be compounded by using the extruder machine to produce new composites with respect to the percentage of rule of mixture. The new composite will be testing with injection molding consecutively to test with the tensile testing to investigate the behaviour of the composites. The influence of the reinforcement into the performance of the composites is also determined by the mechanical properties of the tensile strength and tensile modulus. [3]

## **CHAPTER 2: LITERATURE REVIEW**

### **2.1 Composite Materials**

Composite materials for construction, engineering, and other related applications are produced by combine two or more materials in such a way that the elements of the composite materials are not fully blended. Composite materials take improvement of the special strengths and capacities of different materials that use as the reinforcement. In the case of palm oil fibers and rice husks, they use the natural waste as material to reinforce with the polymer. Typically, reinforcing materials are strong with low densities while the matrix is usually a ductile, or tough, material. If the composite is designed and fabricated correctly, it combines the strength of the reinforcement with the toughness of the matrix to achieve a combination of desirable properties not available in any single conventional material. Now a day, there have been investigating the composite materials to build stronger and lighter objects for industries application.

The common of composite materials use two elements which is a matrix and reinforcement. The reinforcement material is should be stronger and stiffer to form a kind of backbone, while the matrix will keeps the reinforcement in a position. The matrix also protects the reinforcement, which may be brittle or ductile. Generally, composite materials have excellent compressibility combined with good tensile strength, making them flexible in a wide range of situations. The common composite materials can be classified as follows: [4]

1. Fibers as the reinforcement (Fibrous Composites)
2. Particles as the reinforcement (Particulate composites)
3. Flat flakes as the reinforcement (Flake composites)
4. Fillers as the reinforcement (Filler composites)

## 2.2 Fibers as the reinforcement (Fibrous Composites)

Composite plastics is classified to the types of plastics that result from bonding two or more homogeneous materials with different material properties to obtain a final product with certain desired material and mechanical properties. Fiber reinforced plastics are a category of composite plastics that specifically use fibrous materials to mechanically enhance the strength and elasticity of plastics. The original plastic material without fiber reinforcement is known as the matrix. The matrix is a tough but relatively weak plastic that is reinforced by stronger stiffer reinforcing filaments or fibers. The extent that strength and elasticity are enhanced in a fiber reinforced plastic depends on the mechanical properties of the fiber and matrix, their volume relative to one another, and the fiber length and orientation within the matrix. Reinforcement of the matrix occurs by definition when the Fiber Reinforcement material exhibits increased strength or elasticity relative to the strength and elasticity of the matrix alone. [4]

## 2.3 EFBF as Reinforcement

Palm fiber is natural fiber extracted from palm oil bundles in the empty fruit bunch. During the manufacturing process of palm fiber, EFB are shredded, separated, refined and dried. The manufacturing process does not involve chemical process or exposure. Table 1 below shows the characteristic of palm oil fiber. [5]

**Table 1: Characteristics of oil palm empty fruit bunch fiber [5]**

<b>Lignin content (%)</b>	<b>Cellulose content (%)</b>	<b>Density (g/cc)</b>	<b>Average Diam. (<math>\mu</math>m)</b>	<b>Ash content (%)</b>
<b>19</b>	65	0.7–1.55	150–500	2

## 2.4 Polystyrene as Matrix

Polystyrene is an aromatic polymer made from the aromatic monomer styrene, a liquid hydrocarbon that is commercially manufactured from petroleum by the chemical industry. Polystyrene is one of the most widely used kinds of plastic. Polystyrene is a thermoplastic substance, normally existing in solid state at room temperature, but melting if heated for molding or extrusion, and becoming solid again when cooling off. Pure solid polystyrene is a colorless, hard plastic with limited flexibility.

This information used to determine the temperature for the compounding and injection molding process. With the melting temperature of the PS, we can adjust the temperature so the defect during the process can be reduce to ensure the quality of the composite that will be produce is excellent. Table 2 shows the properties of polystyrene; which is can evaluate the result from the tensile test between pure polymer and polymer reinforced to study the changes in mechanical properties of the reinforced material. [6]

**Table 2 : Properties of the Polystyrene [6]**

<b>Properties</b>	
<b>Density</b>	1050 kg/m <sup>3</sup>
<b>Density of EPS</b>	25-200 kg/m <sup>3</sup>
<b>Young's modulus (<i>E</i>)</b>	3000-3600 MPa
<b>Tensile strength (<i>s<sub>t</sub></i>)</b>	46-60 MPa
<b>Elongation at break</b>	3-4%
<b>Melting point</b>	240 °C

## **2.5 Fiber Length**

The effectiveness of the fiber reinforcement is depend on several factor including the type of resin used, the quantity of fiber in resin matrix, length of fibers, form of fibers, direction of fiber adhesion of fiber to polymer matrix and impregnation of fibers with resin. Load transfer from matrix to the fiber with short fibers composites and fiber adhesions. The critical fiber length is known as the shortest effective fiber length.

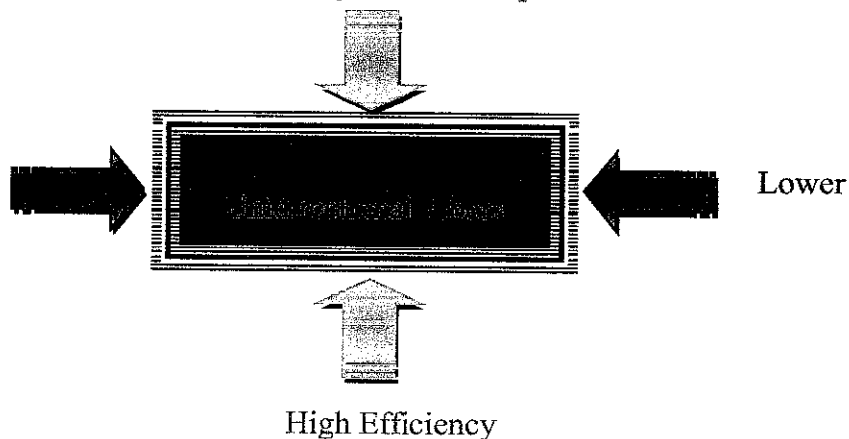

## **2.6 Fiber Volume Fraction**

The fiber volume of a composite material may be determined by chemical matrix absorption, which is the matrix is dissolved and the fibers weighed and calculated from substituent weights and densities technique may be used and the volume fraction determined as the area fraction of each constituent. It has been described by increasing the fiber content the tensile strength increases linearly according to the law of mixtures. It is preferable to define the fiber quantity in the polymer matrix in volume percentage rather than weight percentage. [7]

## 2.7 Fiber Orientation

It is known when the directional orientation of the fiber is with their long axis and perpendicular to an applied force the result is a high reinforcing effect. However, forces that are perpendicular to the long axis of the fibers produce matrix-dominated failures and, consequently, result in low reinforcing efficiency. Multi-directional fiber reinforcement has been employed to minimize the anisotropic behavior of unidirectional fiber reinforcement. On the other hand, multidirectional fiber reinforcement is accompanied by a decrease in strength when compared with unidirectional fibers. [8]

**Figure 1: Reinforcing efficiency of unidirectional fibers is direction dependent (anisotropic) [8]**

Composites that have randomly-oriented fibers are isotropic in their mechanical and physical properties. In other words, the strength of the fiber-reinforced composite (FRC) is not related to the direction of the stress. It can be supposed the two fiber systems could be used in different clinical applications, where different properties are required.

**Figure 2: Reinforcing efficiency of multidirectional fibers is not direction dependent (isotropic) [8]**

## 2.8 Determination of Rule of Mixture

In the fiber reinforced material the fibers are distributed throughout the matrix in a pattern that can be describe as repeating. [9]

$$M_c = M_f + M_m \quad (1)$$

$$V_f = \frac{M_f}{\rho_m} \quad (2)$$

$$V_m = \frac{M_m}{\rho_m} \quad (3)$$

$$V_c = V_f + V_m \quad (4)$$

$$v_f = \frac{V_f}{V_c} \quad (5)$$

Where

$M_c$  = Mass of composite specimen, (g)

$M_f$  = Mass of EFBF, (g)

$M_m$  = Mass of matrix, (g)

$\rho_f$  = Density of EFBF, (g/cm<sup>3</sup>)

$\rho_m$  = Density of matrix, (g/cm<sup>3</sup>)

$V_c$  = Volume of composite specimen, (cm<sup>3</sup>)

$V_f$  = Volume of EFBF, (cm<sup>3</sup>)

$V_m$  = Volume of matrix, (cm<sup>3</sup>)

$v_f$  = Composite volume fraction

## 2.9 Stress strain curve

The tensile modulus is the ratio of stress to elastic strain in tension. A high tensile modulus means that the material is rigid - more stress is required to produce a given amount of strain. In polymers, the tensile modulus can be close or may vary widely. This variation may be 50% or more, depending on resin type, reinforcing agents, and processing methods. The stress  $\sigma$  in the material increases but, because of the decrease in the cross-sectional area  $A$ , the stress  $S$  calculated from the load and the original cross-sectional area  $A$ , increases more slowly, attains a maximum value  $S$ , and usually declines before the specimen breaks. Refer figure 7 for the detail of the tensile modulus using the stress strain curve. [10]

Figure 3: Stress Strain Curve of Plastic

## 2.10 Properties obtained from the tensile test

### 2.9.1 Yield strength

When the stress was applied to the material, the material inhibits elastic deformation. The strain that develops is completely recovered when the applied stress is release. However, if the stress is continued to apply, the material tend to exhibit both elastic and plastic deformation. The critical stress value is needed to initiate plastic deformation is defined as the elastic limit of the material. [10]

### 2.9.2 Stiffness

A qualitative measure of the elastic deformation produces in a material. A stiff material has a high modulus of elasticity. The stiffness,  $k$ , of a material is defined by: [10]

$$k = \frac{P}{\delta} \quad (6)$$

Where:

$P$  is the applied force

$\delta$  is the deflected distance

As both the applied force and deflection are vectors (respectively  $P$  and  $\delta$ ), in general their relationship is characterized by a stiffness matrix,  $k$ , where:

$$P = k\delta \quad (7)$$

The deflections in general, refer to a point distinct from that where the force is applied and a complicated structure will not deflect purely in the same direction as an applied force. The stiffness matrix enables such systems to be characterized in straightforward terms.

## 2.11 Relationship to elasticity (Modulus of Elasticity)

In general, elastic modulus is not the same as stiffness. Elastic modulus is a property of the constituent material where stiffness is a property of a solid body. That is the modulus is an intensive property of the material, stiffness, which is an extensive property of the solid body dependent on the material and the shape and boundary conditions. [10]

$$k = \frac{AE}{L} \quad (8)$$

Where:

$A$  is the cross-sectional area,

$E$  is the Young's modulus,

$L$  is the length of the element.

## CHAPTER 3: METHODOLOGY

### 3.1 Research Methodology

#### 3.1.1 (EFBF) Preparation

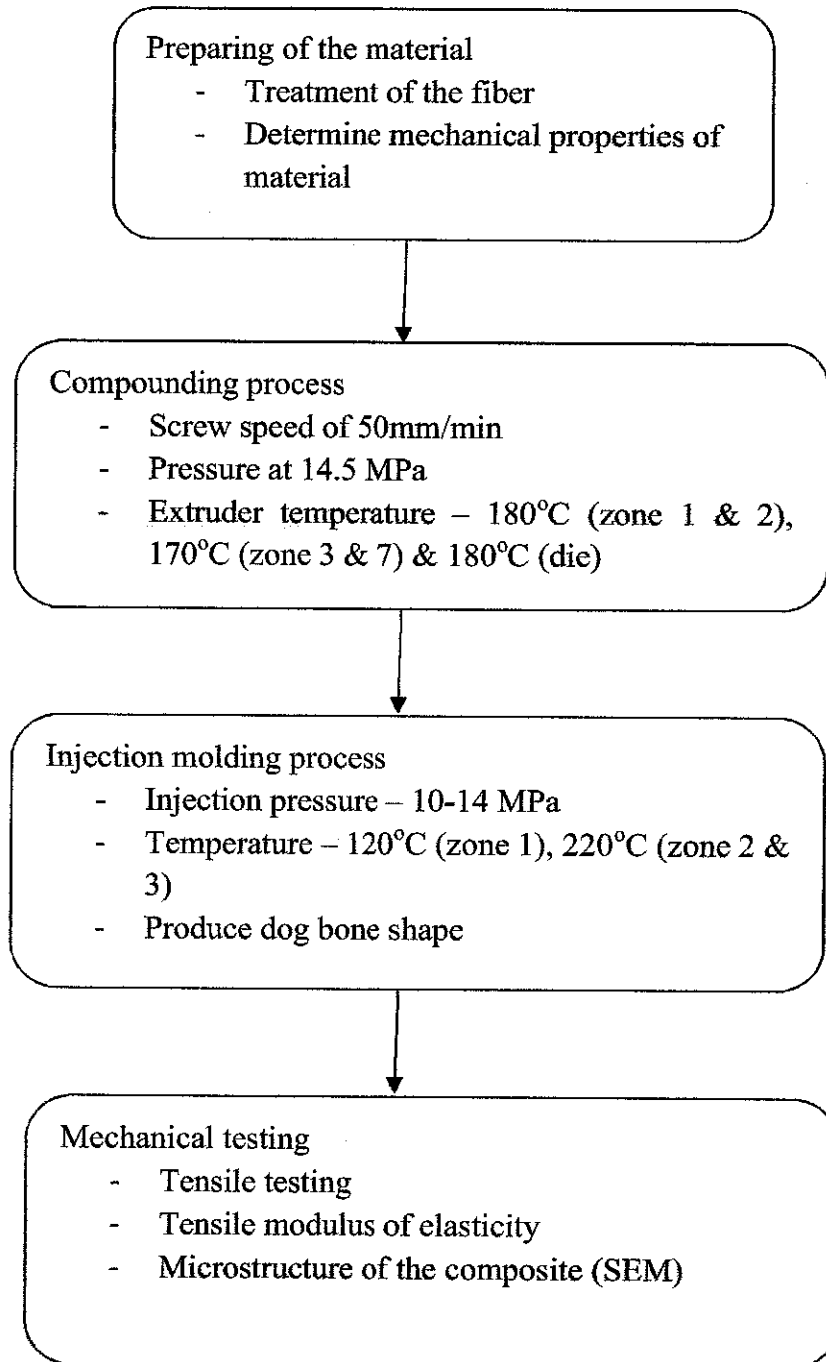

Oil palm empty fruit bunch (OPEFB) fibers have been collected from local palm oil factory which is from Kilang Kelapa Sawit Lekir Sdn. Bhd. The fiber will be washed thoroughly with 2.0% alkaline to remove the adhered and contaminants. The fibers have been oven dried for one day for 100°C to remove moisture trapped in the fiber. After that the fiber have been granulate by using the granulator to make the fiber as powder. Below is the flow chart that shown the procedure that will be using to prepare the fiber.

**Figure 4: Flow diagram of the preparation of the Fibers**

### 3.1.2 Flow of the process

Figure 5 shows the flow of the process from treatment of the fiber until mechanical testing of the reinforced composite.

**Figure 5: Flow diagram of process of making the composites and the testing**

### 3.1.3 Fiber Volume Fraction

Based on the formula that given before, the volume fraction of the polystyrene and fiber have been determine in order to verify the mass of polystyrene and fiber that will be using for the compounding and injection molding. Table 3 below shows the volume fraction for the fiber and polystyrene.

Basis weight of the composites we assume about **500 g** the theoretical value for the weight that ideal for the compounding and injection molding process.

Density of the EFBF: **1.15 g/cm<sup>3</sup>**

Density of the PS: **1.05 g/cm<sup>3</sup>**

**Table 3: List of the % of Volume Fraction.**

No of exp	% of the fiber	% of the PS	Vol of fiber (cm <sup>3</sup> )	Vol of PS (cm <sup>3</sup> )
1	0	100	0	476.19
2	5	95	21.74	452.38
3	10	90	43.48	428.57
4	15	85	65.22	404.76
5	20	80	86.96	380.95

### 3.1.4 Fiber Weight Fraction

Base from the Fiber Volume Fraction, the amount that will be used can be determined by using the weight fraction. This weight will be use to find the exact amount for each percentage of fiber and Polystyrene. From the equation shown below, the weight can be calculated.

$$weight_{fiber} = vol_{fiber} \times \rho_{fiber}$$

$$weight_{PS} = vol_{PS} \times \rho_{PS}$$

**Table 4 : List of the % of Weight Fraction.**

No of exp	% of the fiber	% of the PS	Wt of fiber (g)	Wt of PS (g)
1	0	100	0	500
2	5	95	25	475
3	10	90	50	450
4	15	85	75	425
5	20	80	100	400

### 3.1.5 Compounding

A dry blends of polystyrene and EFBF is fed to the extruder for mixing. The strand-coating method consists of passing the roving or tows of fibers through extruder to coated and impregnated by the molten polystyrene. The impregnated fiber tow is cooled in a water bath and then chops into required length. Figure below show the Extruder Machine that will be use for the compounding process of the EFBF and Polystyrene. The percentage of volume fraction is need to precise since the fiber especially will be degraded and burn during the compound process.

**Figure 6 : Composites after compound**

### 3.1.6 Properties of Extruder and Injection Molding

<b>Cycle time</b>	<b>30.00 s</b>

### 3.1.7 Injection Molding

All the compounds that produced by the extruder machine were transferred to the injection molding machine. The compound is fed to the machine through the hopper. The compound enter the injection barrel by gravity though the feed throat. Upon entrance into the barrel, the resin is heated to the appropriate melting temperature. The resin is injected into the mold by a reciprocating screw. Therefore, the temperature for the injection molding can be reduce since the melting temperature of the fiber is low compare to the polystyrene. This process is to avoid burning during the injection molding process. For this type of testing, it produces the dog-bone shape specimens for following mechanical testing. [11].

**Figure 7: Injection Molding Machine**

## 3.2 Mechanical Testing

### 3.2.1 Tensile Testing

A standard test piece is gripped at either end by suitable apparatus in a testing machine which slowly exerts an axial pull so that the steel is stretched until it breaks. Tensile tests provide different measures of the material's mechanical properties. The tensile test gives a measure of the Young's modulus of the material as well as the tensile strength and yield point. The load required for the flex test is usually much lower which less than 2000N. Injection molded test samples were provided for this experiment. In order to give accurate results, the tensile samples should not have notches or burrs on their edges and should be free of scratches. Test was performed until tensile failure occurred. Figure below show the tensile test machine that will be used to test the strength of the composite that have be produce in dog bone shape by injection molding process. [12]

**Figure 8: Tensile Test Machine**

### 3.3 Microstructure Fracture of the Composites

Figure below is the SEM machine. The **scanning electron microscope (SEM)** is a type of electron microscope that examines the images of sample surface by scanning it with a high-energy beam of electrons. The electrons interact with the atoms that make up the sample producing signals that contain information about the sample's surface topography, composition and other properties such as electrical conductivity. The SEM has a large depth of field, which allows a large amount of the sample to be in focus at one time. The SEM also produces images of high resolution, which means that closely spaced features can be examined at a high magnification. Preparation of the samples is quite easy since most SEMs only require the sample to be conductive. When a tensile stress is applied along the fibers, it deforms in a brittle manner, with void formation and eventually produces a dimple fracture surface. Fracturing will be happen if the bonding between the fiber and matrix is poor. Void can form between the fiber and the matrix and cause the pull-out. [12]

**Figure 9: Scanning Electromagnetic Microscopic**

## CHAPTER 4: RESULT AND DISCUSSION

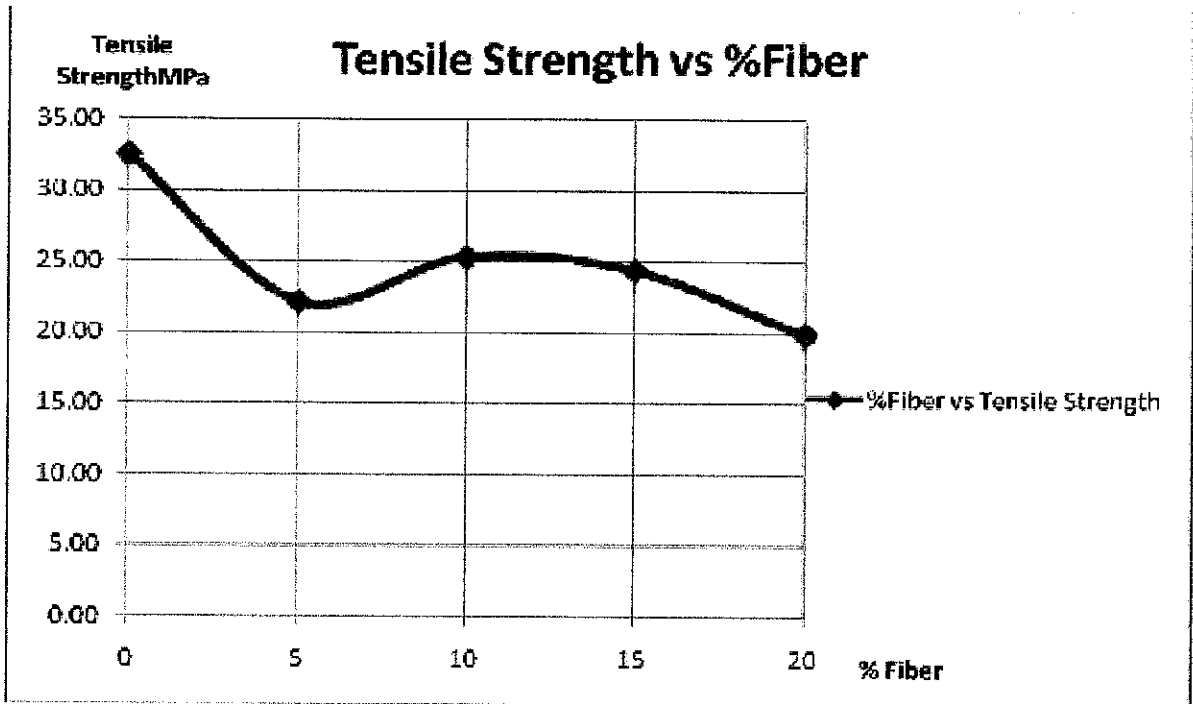

### 4.1 Mechanical Properties of Tensile Testing

**Table 7 : Tensile Testing Properties**

Properties of the Tensile Test					
% of fiber	Stiffness (kN/m)	Young Modulus (MPa)	Tensile Strength (MPa)	Load at Maximum (N)	Extension at Maximum (mm)
0%	535	1072.8	32.52	1301.2	6.015
5%	379	768.0	22.20	887.79	3.8508
10%	532	1077.3	25.35	1014.0	3.7168
15%	580	1174.0	24.42	976.73	3.0471
20%	231	467.6	19.92	796.65	5.3107

From table 7, it shows the summary of the mechanical properties that obtained from the tensile testing, the comparison between the 100% of Polystyrene and reinforced composite materials can be classified by plotting the graphs.

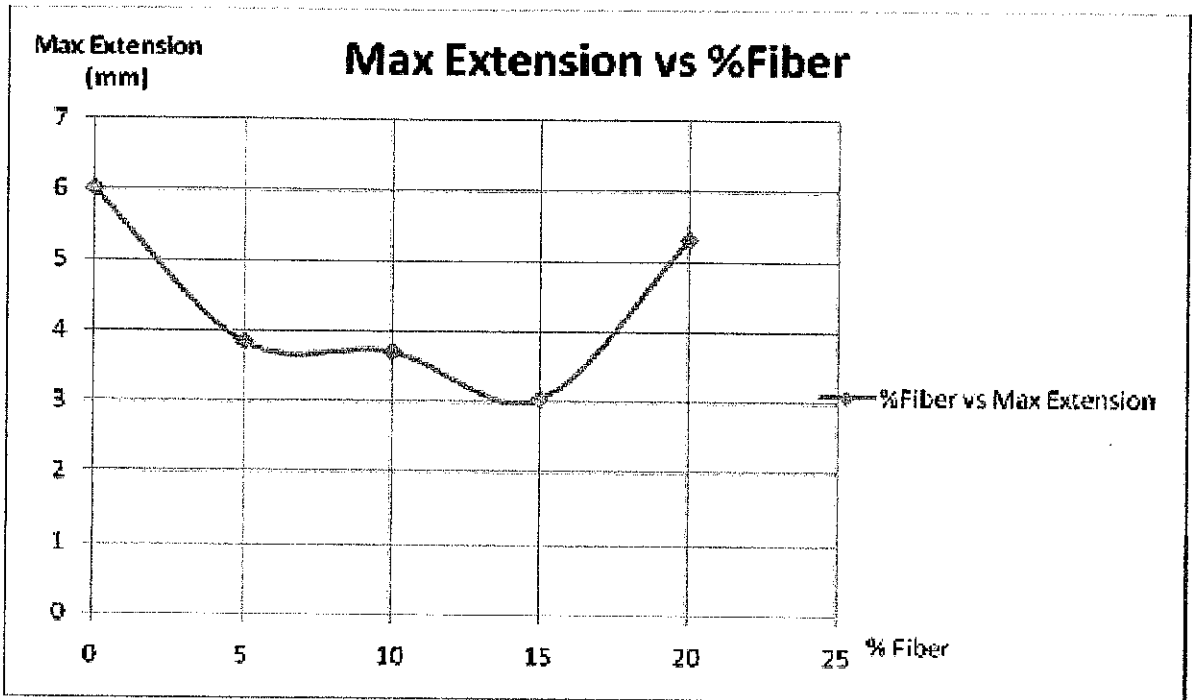

#### 4.2 Graph of the tensile properties vs. percentage of fiber

**Figure 10: Graph of Tensile Strength vs. % Fiber**

Fiber-reinforced composites revealed declining elongation at break values with fiber content increasing. An approximately 80– 90% reduction was recorded at 15% fiber content compared to the pure polystyrene (Fig. 14). Stiffness or modulus was found to increase consistently with fiber content (Fig. 15). The modulus of a short fiber composite depends on several factors, including fiber length, fiber orientation, fiber and matrix volume fractions, as well as modulus of both components.

**Figure 11: Max Extension vs. %Fiber**

**Figure 12: Graph of Stiffness vs. % Fiber**

Reinforced materials with higher Fiber Volume Fractions (FVF) in a composites material were having large gaps between the fiber bunches. Fiber diameter is an important factor here with the smaller diameter fibers were provide higher fiber surface areas, spreading the fiber and matrix interfacial loads. As a general rule, the stiffness and strength of a composite material will increase in proportion to the amount of fiber present. However, at 20% FVF which is depend on the technique the fibers pack together although tensile stiffness may continue to increase, the composite material's strength will reach a peak and then begin to decrease due to the lack of sufficient resin to hold the fibers together properly.

### 4.3 SEM morphological study

Figures (13-14) show SEM micrograph of the tensile test surfaces in the Polystyrene. There is a clear evidence of brittle failure in the 100% of Polystyrene sample. In this sample, only the brittle fracture can be identify since there is no interactions between polymer and fiber yet.

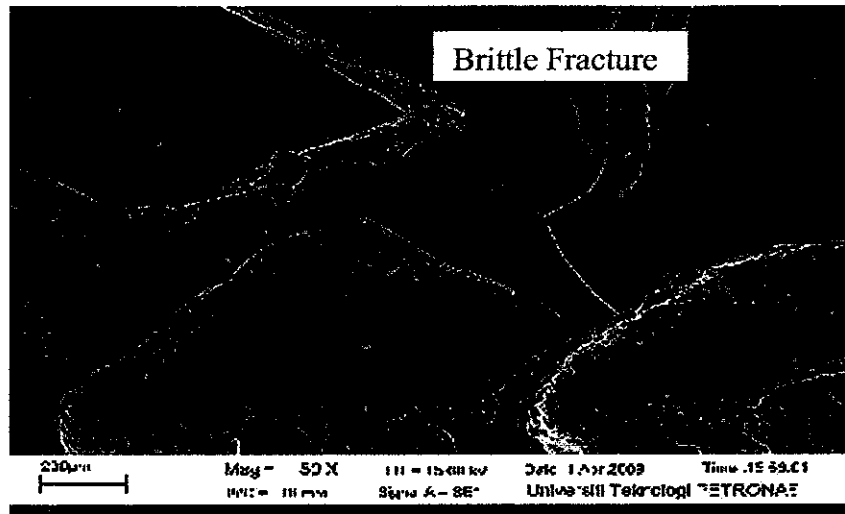

Figure 13: SEM micrograph shows tensile test surface of 100% of Polystyrene

Figure 14: SEM micrograph shows brittle surface of 100% of Polystyrene

**Figure 15: SEM micrograph shows weak bonding in 5% fiber composites**

There clear fracture surface shows poor fiber or matrix interfacial bonding between the fibers and PS matrix. The weak bonding between the fiber and polymer cause by the improper preparation of the material and also not using the proper coupling agent to bond the material. In figure 18 shows the length of the fiber,  $925.1\mu$  which is can be categorize as long fiber and the diameter of the fiber is  $106.2\mu$ . In other words, as expected for good fracture mechanics results, the interfacial toughness was independent of both fiber length and fiber diameter.

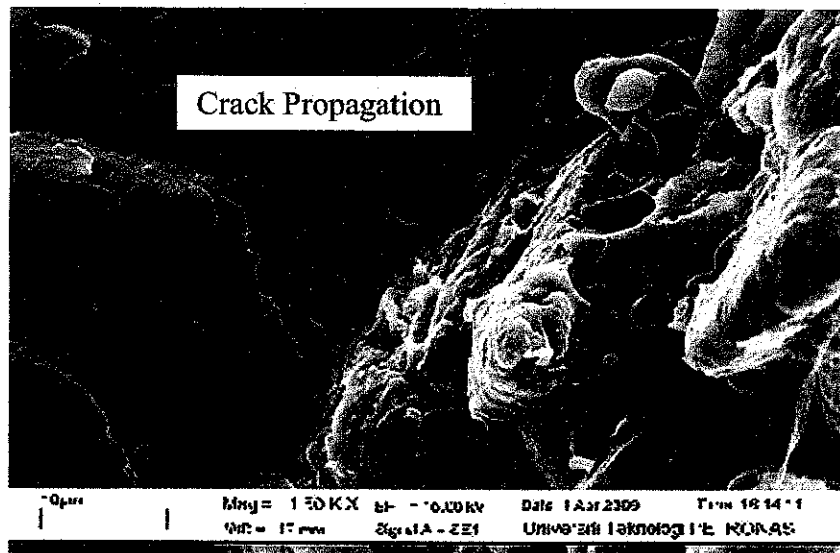

**Figure 16: SEM micrograph shows fiber length in 5% fiber composites**

**Figure 17 : SEM micrograph shows fiber pull out in 10% fiber composites**

According to the SEM fractographs (Fig. 17-18), fiber pull-out and debonding predominate in fracture surfaces with fairly clean and recognizable fiber surface without matrix adherence. Crack propagation in fiber reinforced composites is run by link stresses provided by fibers along the crack. The behavior of fiber reinforced structural components under general loading conditions which are where mixed mode crack propagation is possible and the normal and shear stresses acting on a crack are a function of crack opening and shearing displacements.

**Figure 18: SEM micrograph shows crack propagation in 10% fiber composites**

**Figure 19 : SEM micrograph shows fiber debonding in 15% fiber composites**

From figure 22 and 23, the interfacial debonding between fibers and the matrix may occur under increasing deformations and influence the overall stress-strain behavior of composite materials. After the interfacial debonding, the debonded fibers may lose the load-carrying capacity in the debonded direction (Zhao and Weng 1996, 1997). Yet, they are still able to transmit internal stresses into the matrix through the bonded portion and are regarded as partially debonded fibers (Zhao and Weng 1996, 1997). It can be assumed that the debonding of fibers is controlled by the stress of the fibers and the statistical behavior of the fiber-matrix interfacial strength. [13]

**Figure 20: SEM micrograph shows weak bonding in 15% fiber composites**

**Figure 21 : SEM micrograph shows bubbles in 20% fiber composites**

From SEM micrograph, the samples show voids and bubbles which are one of the failures that could be occurring during the manufacturing process. From figure (21&22) it shows a lot of bubble at the tensile test surface. For the percentage fiber of 20%, we can see that the contact of fiber and matrix are weak since the fiber burn during the compounding. The composite become more brittle and burn during the injection molding process.

**Figure 22: SEM micrograph of 20% fiber composites**

## CHAPTER 5: CONCLUSION

This study of the palm oil fiber as reinforcement to the polystyrene is potentially to enhance the capability of the polymer composites. The mechanical properties of the composites may be further enhanced by using suitable bonding agents and proper method to make it accomplish and improve the bonding between the palm oil fiber with and polymer matrix. The particle size and distribution strongly affects the damage mechanisms of the composite due to increased stress levels in the matrix between the particles in the matrix between the particles. From the result shown that when the fiber volume fraction increase by 5%, the tensile strength of the reinforced composites is decreasing due to the quantity of the fiber added into the polymer. It is led to the weak bonding between the fiber and matrix. The modulus and the stiffness of the composites show the increasing when the fiber volume fraction is increase from 10% to 15% of fiber. Then the properties of composite show the declining at 20% of fiber. The interfacial bonding of the composites shows the weak bonding between fiber and matrix due to the improper preparation of the material. As conclusions, this project shows the successful study of the effect of fiber volume fraction to the mechanical properties of the composites materials. It shows the dissimilarity between the tensile strength, modulus of elasticity and stiffness of the composite when the volume fraction increase by 5%. But, when the fiber volume fraction at 20% reached, the fiber shows the failure to bond with matrix due to the proportion of the composites.

## **CHAPTER 6: RECOMMENDATION**

As for the recommendation for this project, the weak bonding can be improved by using the coupling agent such as Silane Coupling Agents and Titanate Couplers. Coupling agent is a chemical substance that capable to react with both the reinforcement and the resin matrix of a composite material to form or promote a stronger bond at the interface. Other than that, the study of fibrous composites can be change into filler composites since using the fiber can cause burning during the process. The treatment of the fiber should decrease the weight and become lighter than matrix. It is also can be recommend to change the matrix by using the low melting point of polymer. The suitable matrix that can be used is the polystyrene epoxy resin.
